Haemoflagellates of Sloths, The (J. J. Shaw), *review* by P. C. C. Garnham, 291
Handbook of Gas Laser Experiments (G. L. Rogers), *review* by Alan P. Anderson, 1179
Handbook of Molecular Cytology (Edit. by A. Lima-de-Faria), *review* by John Tooze, 878
Handbuck der Zoologie (Willy Kukenthal), *review* by R. A. Crowson, 1070
History of Adult Education in Great Britain (Thomas Kelly), *review* by W. E. Styler, 979
Hot Brines and Recent Heavy Metal Deposits in the Red Sea (Edit. by Egon T. Degens and David A. Ross), *review* by D. H. Matthews, 44
Human Vigilance Performance (D. R. Davies and G. S. Tune), *review* by Keith Oatley, 188
Immunity to Parasitic Animals (Edit. by G. J. Jackson, Robert Herman and Ira Singer), *review* by R. J. Terry, 291
Immunoassay of Gonadotrophins (Edit. by E. Diczfalusy), *review* by May Reed, 668
Immunogenetics of Tissue Transplantation (A. Lengerov), *review* by Leslie Brent, 667
Immunology and Development (Edit. by Matteo Adinolfi), *review* by G. A. Guthrie, 982
Induced Mutation in Plants, *review* by G. R. Mackay, 666
Industrial Research and Technological Change (E. Mansfield), *review* by C. Freeman, 39
Information, Mechanism and Meaning (Donald M. MacKay), *review* by Christopher Longuet-Higgins, 287
International Journal of Biochemistry, The, *review* by J. H. Morris, 51
International Journal of Bio-Medical Computing, *review* by C. C. Spicer, 569
Introduction to Advanced Organic Chemistry (P. J. Durrant and B. Durrant), *review* by J. W. Linnett, 1178
Introduction to Mineralogy (Carl W. Correns), *review* by I. D. Muir, 292
Introduction to the Chemistry of Enzyme Action (A. Williams), review by Peter H. W. Butterworth, 191
Introduction to the General Theory of Particle Transfer (V. Kourganoff), *review* by I. P. Grant, 670
Introduction to the Solar Wind (J. C. Brandt), *review* by David W. Hughes, 1275
Introduction to X-Ray Crystallography (M. M. Woolfson), *review* by H. Lipson, 982
Ion Exchange and Solvent Extraction of Meat Complexes (Y. Marcus and A. S. Kertes), *review* by H. M. N. H. Irving, 192
Is the Business Cycle Obsolete? (Edit. by M. Bronfen Brenner), *review* by Derek H. Aldcroft, 773
John Hunter (Jessie Dobson), *review* by K. Bryn Thomas, 59
Journal for the History of Astronomy, *review* by J. V. Pepper, 471
J. Sen Memorial Volume (Edit. by H. Santapau, A. K. Ghosh, S. K. Roy, S. Chanda and S. K. Chaudhuri), *review* by William S. Lacey, 776
Laboratory Techniques in Membrane Biophysics (Edit. by H. Passow and R. Stampfli), *review* by J. B. Finean, 52
Land and Landscape (Brenda Colvin), 40
Landslides and their Control (Quido Zaruba and Vojtech Mencl), *review* by G. A. Kellaway, 47
Learn Limits Through Problems (S. I. Gelfand, M. L. Gerver, A. A. Kirillov, N. N. Konstantinov and A. G. Kushnirenko), 671
Life of Reptiles, The (Angus Bellairs), *review* by Garth Underwood, 1272
Limits and Continuity (P. P. Korovkin), *review* by L. S. Goddard, 671
Liquid Crystals and their Applications (Thomas Kallard), *review* by G. W. Gray, 983
London's Green Belt (David Thomas), *review* by Terence Bendixson, 1173
Lubrication and Wear in Joints (Edit. by Verna Wright), *review* by C. G. Woods, 777
Malays of South-West Sarawak before Malaysia, The (Tom Harrisson), *review* by W. D. Wilder, 35
Man and Animal in the Zoo (Heini Heidiger), *review* by L. Harrison Matthews, 38
Man and Food (Magnus Pyke), *review* by N. W. Pirie, 665
Marc Isambard Brunel (Paul Clements), *review* by Nigel Hawkes, 39
Marine Biology (Herman Friedrich), *review* by Derek Dorsett), 1176
Mass Transfer in Heterogeneous Catalysis (Charles N. Satterfield), *review* by D. L. Trimm, 1179
Mathematical Problems (E. B. Dynkin, A. A. Molchanov, A. L. Rozental and A. K. Tolpygo), *review* by L. S. Goddard, 671
Measurement of the Faeces (Michael Joseph and Carol Dawbarn), *review* by R. McL. Todd, 1177
Mechanisms of Urine Concentration (S. E. Dicker), *review* by D. B. Moffat, 567
Mediators of Cellular Immunity (Edit. by H. Sherwood Lawrence and Maurice Landy), *review* by D. A. L. Davies, 774
Megaloblastic Anaemias, The (I. Chanarin), *review* by H. B. Goodall, 381
Memories (Julian Huxley), *review* by Gavin de Beer, 979
Metaphysics and the Philosophy of Science (G. Buchdahl), *review* by Maurice Mandelbaum, 40
Methods of Molecular Quantum Mechanics (R. McWeeny and B. T. Sutcliffe), *review* by E. Theal Stewart, 383
Millimetre and Submillimetre Waves (Edit. by F. A. Benson), *review* by P. J. B. Clarricoats, 1275
Mind, Brain and Adaptation in the Nineteenth Century (R. M. Young), *review* by Norman Geschwind, 665
Mineral Kingdom, The (P. E. Desautels), *review* by John R. V. Brooks, 45
Mineral Metabolism (Edit. by C. L. Comar and Felix Bronner), *review* by B. E. C. Nordin, 290
Mineralogical Applications of Crystal Field Theory (Roger G. Burns), *review* by P. Henderson, 45
Molecular Assymetry in Biology (Ronald Bentley), *review* by W. Klyne, 566
Multicompartment Models for Biological Systems (G. L. Atkins), *review* by E. W. Emery, 667
Multiple Equilibria in Proteins (Jacinto Steinhardt and Jacqueline A. Reynolds), *review* by Sherry Lewin, 1273
Multiple-Beam Interference Microscopy of Metals (S. Tolansky), *review* by W. T. Welford, 1179
Muscles and Movements (M. A. MacConaill and J. V. Basmajian), *review* by E. C. B. Hall-Craggs, 668
My Life (Otto Hahn), *review* by Egon Bretscher, 1065
Natural History of the Lake District (Edit. by Canon G. A. K. Hervey and J. A. G. Barnes), 56
Neurobiology of Cerebeller Evolution and Development (Edit. by R. Llinás), *review* by K. E. Webster, 1176
Nightshades (Charles B. Heiser, jun.), *review* by A. R. Perry, 55
Nuclear Electronics (E. Kowalski), *review* by Lindsay Molyneux, 778
Nuclear Reactions (I. E. McCarthy), *review* by Daphne F. Jackson, 879
Numerical Methods for Partial Differential Equations (William F. Ames), *review* by A. H. Craven, 1276
Nutrition in Preschool and School Age (Edit. by Gunnar Blix), *review* by C. Eric Stroud, 190
Occupational and Environmental Cancers of the Urinary System (W. C. Hueper), *review* by D. M. Wallace, 290
Oceanography (Peter K. Weyl), *review* by J. P. Riley, 1274
Optimum Population for Britain, The (Edit. by L. R. Taylor), *review* by D. R. Cope, 1269
Organic Chemistry of Secondary Plant Metabolism (T. A. Geissman and D. H. G. Crout), *review* by T. W. Goodwin, 1175
Palaeopathology (Paul A. Janssens), *review* by H. Hughes, 380
Parasitism and Symbiology (Clark P. Read), *review* by R. A. Wilson, 982
Partners in Science (Edit. by Eric Robinson and Douglas McKia), review by Robert Fox, 41
People and the Countryside (H. E. Bracey), *review* by Geoffrey Berry, 1174
Perils of the Peaceful Atom (Richard Curtis and Elizabeth Hogan), *review* by F. R. Farmer, 287
Pharmacology of Synapses, The (J. W. Phillis), *review* by J. F. Mitchell, 1177
Physical and Chemical Aspects of Adsorbents and Catalysts (Edit. by B. G. Linsen), *review* by R. P. H. Gasser, 192
Physical Principles of Ultrasonic Diagnosis (P. N. T. Wells), *review* by C. B. Allsop, 289
Physics of Glaciers, The (W. S. B. Paterson), *review* by John W. Giles, 1274
Physics of Metals, The (Edit. by J. M. Ziman), *review* by E. Roland Dobbs, 48
Physics of the Earth (T. F. Gaskell), *review* by Peter J. Smith, 44
Physics of the Earth (Frank D. Stacey), *review* by Peter J. Smith, 44
Physique Nucleaire/Nuclear Physics (Edit. by C. DeWitt and V. Gillet), 1066
Pictorial Encyclopedia of Insects, The (V. J. Stanek), *review* by Mary Lindley, 56
Pigments in Pathology (Edit. by Moshe Wolman), *review* by I. W. Whimster, 981
Pill, The (Morton Mintz), *review* by D. M. Potts, 187
Plasma Donors (T. J. M. Boyd and J. J. Sanderson), *review* by D. A. Dunnett, 47
Potassium-Argon Dating (G. Brent Dalrymple and Marvin A. Lanphere), *review* by Frank J. Fitch, 473
Prehistoric Europe (Philip Van Doren Stern), *review* by Glyn Daniel, 1270
Prehistoric Russia (T. Sulimirski), *review* by Grahame Clark, 37
Prehistory (Derek Roe), 37
Principles of General Neurology (B. Wyke), *review* by R. A. Henson, 189
Principles of Radiation Chemistry (J. H. O'Connell and D. F. Sangster), *review* by Glyn O. Phillips, 1178
Problems in Systematics of Parasites (Edit. by Gerald D. Schmidt), *review* by S. Prudhoe, 475

Proceedings of the Fourth International Symposium on Electron and Photon Interactions at High Energies (Edit. by D. W. Braben), *review* by Richard Wilson, 983
Properties of Refractory Metals (Walter D. Wilkinson), *review* by J. G. Ball, 778
Protein-Calorie Malnutrition (Edit. by A. von Muralt), *review* by A. E. Bender, 191
Psychiatry in Medicine (Denis Hill), *review* by G. M. Carstairs, 189
Psychotomimetic Drugs (Proceedings), *review* by D. W. Straughan, 1069
Pulse Radiolysis (Max S. Matheson and Leon M Dorfman), *review* by G. Arthur Salmon, 1066
Radio Emission of the Sun and of the Planets (V. V. Zheleznyakov), *review* by R. D. Davies, 471
Raw and the Cooked, The (Claude Lévi-Strauss), *review* by Peter Rivière, 875
Reagents for Organic Synthesis (Mary Fieser and Louis Fieser), *review* by Ian Fleming, 1178
Recent Advances in Forensic Pathology (Edit. by Francis E. Camps), *review* by Keith Simpson, 189
Red Cell Membrane (Edit. by G. A. Jamieson and Tibor J. Greenwalt), *review* by J. B. Finean, 1070
Reticulo-endothelial System, The (A. E. Stuart), *review* by Ian Carr, 382
Ribosome, The (A. S. Spirin and L. P. Gavrilova), *review* by M. Spencer, 52
Schering Symposium on Mechanisms involved in Conception (Edit. by Gerhard Raspé), *review* by B. D. Bavister, 567
Science in Archaeology (Edit. by Don Brothwell and Eric Higgs), *review* by Barry Cunliffe, 380
Science of Moiré Patterns (Gerald Oster), 49
Second Course in Mathematical Analysis, A (J. C. Burkill and H. Burkill), *review* by T. A. A. Broadbent, 570
Secrets of Plant Life (Marcel Sire), *review* by Mary Lindley, 53
Sequences and Combinatorial Problems (S. I. Gelfand, M. L. Gerver, A. A. Kirillov, N. N. Konstantinov and A. G. Kushnirenko), *review* by L. S. Goddard, 671
Sex and Fertility (C. Wood), *review* by R. G. Edwards, 58
Sexual Dimorphism in Fossil Metazoa and Taxonomic Implications (Edit. by G. E. G. Westermann), *review* by F. H. T. Rhodes, 57
Smithsonian Astrophysical Observatory Star Atlas of Reference Stars and Nonstellar Objects (SAO), *review* by Bernard Page., 1190
Smooth Muscle (Edit. by Edith Bulbring, Alison F. Brading, Allan W. Jones and Tadao Tomita), *review* by J. S. Gillespie, 474
Social Interaction (M. Argyle), *review* by R. N. Rapoport, 36
Social Networks in Urban Situations (Edit. by J. Clyde Mitchell), *review* by W. J. Argyle, 875
Solid State Surface Science (Edit. by Mino Green), *review* by F. C. Tompkins, 473
Sourcebook for Petroleum Geology (Robert H. Dott and Merrill J. Reynolds), *review* by W. D. Gill, 46
Stars, The (R. J. Taylor), *review* by John Gribbin, 1276
Status of General Relativity (W. B. Bonner), *review* by William C. Saslaw, 43
Steroid Biochemistry (Erich Heftmann), *review* by J. K. Grant, 878
Stimulation in Early Infancy (Edit. by Anthony Ambrose), *review* by R. S. Illingworth, 1271
Structure and Mechanism in Organic Chemistry (Sir Christopher K. Ingold), *review* by Peter Sykes), 50
Studies in the Vegetational History of the British Isles (Edit. by D. Walker and R. G. West), *review* by C. D. Pigott, 1174
Subatmospheric Decompression Sickness in Man (D. I. Fryer), *review* by D. N. Walder, 777
Surgeons in the Field (John Laffin), *review* by Edwin Clarke, 565
Survey of Chemical and Biological Warfare, A (John Cookson and Judith Nottingham), *review* by Robert Smith, 37
Survey of Cybernetics (Edit. by J. Rose), *review* by John F. Young, 774
Symmetry and Function of Biological Systems at the Macromolecular Level (Edit. by Arne Engström and Bror Strandberg), *review* by W. B. Gratzer, 288
Tailed Amphibians of Europe, The (J. W. Steward), *review* by E. N. Arnold, 475
Techniques in Protein Biosynthesis (Edit. by P. N. Campbell and J. R. Sargent), *review* by Michael Cannon, 51
Termites (P. E. Howse), *review* by J. H. Sudd, 1175
Textbook of Practical Biology, A (George Usher), *review* by E. J. Vinnicombe, 291
Theoretical Foundations of Medical Physics (Willem Klip), *review* by R. G. Gosling and C. B. Allsop), 569
Theory of Fish Population Dynamics as the Biological Background for Rational Exploitation of Fishery Resources (George V. Nikolski), *review* by D. R. Swift, 58
Thermal Physics (Charles Kittel), *review* by A. B. Pippard, 49
Topics in Basic Immunology (Edit. by Michael Sela and Moshe Prywes), *review* by Denis R. Stanworth, 53
Topics in Carbocyclic Chemistry (Edit. by D. Lloyd), *review* by M. V. Sargent, 778
Topological Geometry (I. R. Porteous), *review* by Roger Fenn, 47
Trace Elements in Agriculture (Vincent Sauchelli), *review* by G. W. Cooke, 666
Transfer and Storage of Energy by Molecules (Edit. by George M. Burnett and Alastair M. North), *review* by J. D. Lambert, 50
Treatise on Invertebrate Paleontology (Edit. by Raymond C. Moore), *review* by H. W. Ball, 669
Trends in Clinical Pathology (BMA), *review* by W. A. J. Crane, 980
University Optics (D. W. Tenquist, R. M. Whittle and J. Yarwood), *review* by D. J. Bradley, 292
Urgent Research in Social Anthropology (Edit. by Behari L. Abbi and Satish Saberwal), *review* by Kenneth Ballhatchet, 188
Vascular Plants of the Pacific Northwest (C. Leo Hitchcock, Arthur Cronquist, Marion Ownbey and J. W. Thompson), *review* by Brian T. Styles, 382
Vegetable Staticks (Robert Hales), *review* by J S. Wilkie, 42
Victorian Engineering (L. T. C. Rolt), *review* by Nigel Hawkes, 472
Weather Economics (Edit. by James A. Taylor), *review* by R. W. Gloyne, 193
Wilson Jameson (Neville M. Goodman), *review* by Andrew B. Semple, 565
Boron. Galactic Cosmic Ray Origin of Li, Be and — in Stars (H. Reeves, W. A. Fowler and F. Hoyle), 727
Botany. Three Hundred Years of — in Edinburgh (J. A. Ratter), 904
Bovine Immunoglobulin Light Chain. C-terminal Aminoacid Sequence of — (D. Beale and M. Squires), 1056
Bourdon Tube Rotations. Deep Sea Tide Gauge with Optical Readout of — (J. H. Filloux), 935
Bradford's Law. — and Library Acquisitions (William Goffman and Thomas G. Morris), 922
Bragg, Sir Lawrence. Bragg's Birthday Symposium, *news*, 110
Brain. Long Term Effects of Midbrain Stimulation on 5-Hydroxyindole Synthesis in Rat — (D. Eccleston, I. M. Ritchie and M. H. T. Roberts), 84
  Metabolic Adaptation in the — (Henry McIlwain), 803
  Sexual Differentiation of the —: Effects of Testosterone on Brain RNA Metabolism in Newborn Female Rats (R. B. Clayton, Janice Kogura and Helena C. Kraemer), 810
  Space-Time Transformation on the Frog Cerebellum through an Intrinsic Tapped Delay-line (John A. Freeman and C. N. Nicholson), 640
  Timing of Neuroblast Multiplication in Developing Human — (John Dobbing and Jean Sands), 639
  Unusual Metastasis of a Human Colonic Tumour Xenograft in the Hamster — (David M. Goldenberg), 550
Brain and Memory Biochemistry. Symposium on — at Galesburg State Research Hospital, *news*, 201
Brain Cells. — that Count, *news*, 596
Brain Cell Nuclei. Association of ^{3}H Corticosterone -1,2 with Macromolecules extracted from — (Bruce S. McEwen and Linda Plapinger), 263
Brain Compartmentation. Contribution of the GABA Bypath to Glucose Oxidation, and the Development of Compartmentation in the Brain (A. J. Patel, R. Balazs and D. Richter), 1160
Brain Drain, *parliamentary news*, 491
Brain-Cortex Membrane. Strychnine inhibits the Binding of Glycine to Rat — (Fernando Valdes and Fernando Orrego), 761
BRDC. — Organization, *news*, 203
British Ascidians, *news*, 216
British Isles. *Corophium curvispinum* (Amphipoda) recorded again in the — (H. P. Moon), 976
British Medical Association. — versus the Junior Hospital Doctors Association, *news*, 95
British Museum Library. — Rehousing in Bloomsbury, *news*, 203
British Participation. — in NASA Planetary Research, *news*, 1
British Science. Idyllic if Not Ideal, *Europe*, 1013
British Trust for Conservation Volunteers (BTCV). Formation of —, *news*, 491
Bronchitis. — and Smoking and Air Pollution, *news*, 304
Brood Tending. Pheromone may induce — in the Fire Ant, *Solenopsis saevissima* (B. Michael Glancey, C. E. Stringer, C. H. Craig, P. M. Bishop and B. B. Martin), 863
Brown University. Dr Donald F. Hornig elected President of —, *news*, 9
Bruce, Dr C. E. R. — and Astrophysics (B. C. Lindley), *correspondence*, 985
BTCV. Formation of —, *news*, 491
Building Materials. — from Bagasse, *news*, 489
Burns. *Staphylococcus* sp. Infecting, —, *news*, 1005
Butterfly Conservation (C. Garrett-Jones), *correspondence*, 385

C

Caesium. —, Yttrium and Lanthanum, Superconductivity, *news*, 498
Caesium Clock. Explanation of Apparent Diurnal Variation is — Rates (A. H. Cribbins and L. M. Stephenson), 139
Calcite. — Precipitates at the Soles of Temperate Glaciers (D. C. Ford, P. G. Fuller and J. J. Drake) 441
  High-magnesium Calcite and Protodolomite in Lake Balaton (Hungary) Sediments (German Müller), 749
Calcium. Lanthanum Inhibition of ^{45}Ca Efflux from the Squid Giant Axon (C. van Breemen and P. de Weer), 760
Calcium Levels. Suppression and Enhancement of Antibody Formation by Alteration of the Ca^{2+} Levels (Werner Braun, Masaaki Ishizuka and Philip Seeman), 945
'Campaign GM'. *news*, 198; 793
Canadian Astronomy. New Institute of —, *news*, 591
Canadian Cryptoexplosion Crater. New — at Lake St Martin, Manitoba (K. L. Currie), 839
Canary Islands. East — as a Microcontinent within the Africa—North America Continental Drift Fit (Robert S. Dietz and Walter P. Sproll), 1043
Cancer Cells. Chemotactic Factor associated with Invasion of — (H. Hayashi, K. Yoshida, T. Ozaki and K. Ushijima), 174
  Mitotic Autoregulation of Populations of Normal and Malignant Cells (T. E. Wheldon, W. M. Gray, J. Kirk and J. S. Orr), 547
Cancer Research. — Budget, *news*, 397
  Coordinating Committee on — Set Up, *news*, 1078
  Spin-off from — (Valda M. Craddock), *correspondence*, 1181
Cancer Screening. Women's National Cancer Control Campaign Short of Funds, *news*, 1190
Carbon. Properties and Usage of — for Industry, *news*, 410
Carbon Dioxide Accumulation. Runaway Greenhouse and the — in the Venus Atmosphere, The, (S. I. Rasool and C. de Bergh), 1037
Carbon Fibres. Direct Lattice Resolution of Layer Planes in Polyacrylonitrile Based — (D. J. Johnson), 750
  — Fan Development, Rolls Royce, *news*, 394
  Glassy —, *news*, 315
  Intimate Structure of High Modulus — J. A. Hugo, V. A. Phillips and B. W. Roberts), 144
  Orientation of 3-D Graphite in — (R. A. Coyle, L. M. Gillin and B. J. Wicks), 257
  Properties, Parameters and Preparation of —, *news*, 597
Carbon Isotopes. Reaction of Carbon and Sulphur Isotopes in Apollo II Samples with Solar Hydrogen Atoms (Rainer Berger), 738
Carbon Monoxide. — as a Basis for Primitive Life on Other Planets: a Comment (John Postgate), 978
  — in Space, *news*, 409
Carbon Monoxide Chemical Laser. Constant-Wave Laser Oscillation in a — (Curt Wittig, J. C. Hassler and P. D. Coleman), 845
Carbonate. Geological Significance of Coccoliths in Fine-grained — Bands of Postglacial Black Sea Sediments (David Bukry, Stanley A. King, Michael K. Horn and Frank T. Manheim), 156
  Precipitation of Metastable — Phases from Seawater (K. M. Towe and Philip G. Malone), 348
Carbonic Anhydrase. Directional Correlation Studies of Anomalous Water in — (James C. Glass and George Graf), 635
Carp. Efficiency of Grass Carp (*Ctenopharyngodon idella* Val.) in controlling Submerged Water Weeds (B. Stott and T. O. Robson), 870
Caspian Sea Pollution. — Jeopardises Caviar, *news*, 436
Catalase. Cytochrome Growth and Effect of — on Growth of *Agromyces ramnosus* (Dorothy Jones, John Watkins and David J. Meyer), 1249
Causality. — and Tachyons (J. H. Fremlin), *correspondence*, 194
Caviar. — jeopardised by Oil Pollution in Caspian Sea, *news*, 486
CBI. — Plans for Government Laboratories, *news*, 679
CEGB. — evidence to Select Committee, *news*, 302
Cell Adhesion. Re-examination of a Supposed Case of Specific — (A. S. G. Curtis), 260
Cell Aggregation. Inhibition of — by Antibodies directed against Actomyosin (Bryn M. Jones, Richard B. Kemp and Ute Gröschel-Stewart), 261
Cell Biology Society Symposium. — on Nuclear Activity, *news*, 406
Cell Culture. Virus in — derived from Human Tumour Patients (George J. Todaro, Victor Zeve and Stuart A. Aaronson), 1047
Cell Culture, Insect. Established Insect Cell Line from the Cabbage Looper, *Trichoplusia ni* (W. F. Hink), 466
Cell Division. — in the Early Growth and Morphogenesis of the Chick Limb (Amata Hornbruch and L. Wolpert), 764
  Effect of α-Chlordane on Synchronized Lymphoma Cells and Inhibition of — (P. E. Brubaker, W. G. Flamm and N. J. Bernheim), 548
Cell Division Rate. Comparison of the Effects of LSD. Heliotrine and X-irradiation on Chromosome Breakage, and the Effects of LSD in the — (Y. A. E. Bick) 1165

Cell Hybridization. Plant Protoplasts for Use in Somatic — (W. A. Keller B. Harvey, O. L. Gamborg, R. A. Miller and D. E. Eveleigh), 280
Cell Mediated Immunity. *In vitro* Cytotoxic Test for detecting — to Soluble Antigen (Christopher S. Henney), 1167
Cell Population Regulation. Mitotic Autoregulation of Populations of Normal and Malignant Cells (T. E. Wheldon, W. M. Gray, J. Kirk and J. S. Orr), 547
  Mitotic Autoregulation: a Reply (P. A. Riley), 547
Cell Separation. Two Dimensional —: Comparison of Embryonic and Adult Haemopoietic Stem Cells (J. S. Haskill and M. A. S. Moore), 853
Cell Wall Structure, *news*, 109
Cell Wall Thickness. — Size Distribution, Refractive Index Ratio and Dry Weight Content of Living Bacteria (*Staphylococcus aureus* (Philip J. Wyatt), 277
Cell Wall-Membrane Complexes. DNA Replicating Capacity of Isolated *E. coli* — The (Rolf Knippers and Wolf Stratling), 713
Cells as Solutions. Solubility of Life (H. R. Catchpole), *correspondence*, 1182
Cellular Immune Responses. Inhibition by Hapten of — to a Hapten-Protein Conjugate (Thomas C. Francis and William E. Paul), 173
Cellulase. Induction and the Regulation of Production of — by Fungi (M. A. Hulme and D. W. Stranks), 469
Cementite Films. Fibre-loading Mechanism for the Fracture of — in Ferrite (T. C. Lindley, G. Oates and C. E. Richards), 145
Centaurus A. — X-ray Galaxy, *news*, 898
Centenary. — of Forster's Education Act, *news*, 490
Central Dogma. — Reversed, *news*, 98
Central Inhibition. GABA, Bicuculline and — (D. R. Curtis, A. W. Duggan, D. Felix and G. A. R. Johnston), 1222
Central Nervous System. Chemical Nature of Binding of Serotonin in the — (Spyridon G. A. Alivisatos, Anastasios D. Papaphilis, Frieda Ungar and Prahlad K. Seth), 455
Ceramic Research, *news*, 409
Cerebellum. Space-Time Transformation in the Frog — through an Intrinsic Tapped Delay-line (John A. Freeman and C. N. Nicholson), 640
Cerebral Function Assymetry. Evidence for — in Mice tested for Audiogenic Seizures (Robert L. Collins and Roger Ward), 1062
CERN. Dr Adam's Group Proposals for —, *news*, 301
CERN 300 GeV Accelerator: Costs Fall, Hopes Rise *news*, 1193; Government Decision Awaited on, *news*, 788
Cerumen Types. Human — in Mexico and New Guinea: a Humidity-related Polymorphism in "Mongoloid" Peoples (John M. McCullough and Eugene Giles), 460
Chain Formation. — of Fine Particle Aggregates (D. N. Sutherland), 1241
Chapman, Dr Sydney. The Death of —, *news*, 1187
Chemical and Biological Warfare. Defoliants, *news*, 299
Chemical Industry, *news*, 100
Chemicals in Public Use. Regulation of —, *news*, 299
Chemistry Teaching: in Schools, *news*, 787; Investigation, *news*, 585
Chemotaxis. Chemotactic Factor associated with Invasion of Cancer Cells (H. Hayashi, K. Yoshida, T. Ozaki and K. Ushijima), 174
Chert Pebbles. Some Fossiliferous Pre-Cambrian Chert Pebbles within the Torridonian of Britain (M. D. Muir and J. Sutton), 443
Chimney Design. — to Minimise Atmosphere Pollution, *news*, 584
Chinese Satellite, *news*, 390; 394
  Telemetry from the First Chinese Artificial Earth Satellite (G. E. Perry), 829
Chinese Science, *news*, 390
Chiral Acetates. Fate of — in the Citric Acid Cycle (J. Rétey, J. Lüthy and D. Arigoni), 519
α-Chlordane. Effect of — on Synchronized Lymphoma Cells and Inhibition of Cell Division (P. E. Brunaker, W. G. Flamm and N. J. Bernheim), 548
α-Chlorhydrin. Is Glycidol an Active Intermediate in the Antifertility Action of — in Male Rats (J. D. Hahn), 86
Chloroplasts. Co-factors and —, *news*, 1089
Chloroplast Research. Three Phases of — (D. A. Walker), 1204
Chlorpromazine Metabolites. Sensitive Quantitative Determination of — (Pushkar N. Kaul, Michael W. Conway and Mervin L. Clark), 372
Cholera Toxin. Stimulation of Glycerol Production in Fat Cells by — (Martha Vaughan, Nathaniel F. Force and William B. Greenough, III), 658
Choline Acetyltransferase. Histochemistry at the Light Microscope Level (P. Kása S. P. Mann and Catherine Hebb), 812
  Ultrastructural Localization in Spinal Neurones (P. Kása, S. P. Mann and Catherine Hebb), 814

ERRATA INDEX

Erratum. In the article "A Comparison of Marijuana Users and Non-users" by Norman E. Zinberg and Andrew T. Weil (*Nature*, **226**, 119; 1970), the third sentence in the first column on page 122 should be "There were no signs of overt intellectual deterioration in the C interviewees, . . .".

Erratum. Some corrections should be made to the article "Can Water Polymerize? An Inquiry into the Possible Existence of Strong Bonds between Water Molecules" by Allen P. Minton (*Nature*, **226**, 151; 1970). The first sentence of the second paragraph (p. 151) should read "A modified version of the Iterative Extended Huckel Theory (IEHT)[7,8] has been used to make electronic structure calculations . . .". Equation (1) should read:

$$\mathcal{E}_c = n\mathcal{E}_i + \sum_{i=1}^{n} \mathcal{D}_i + \sum_{i=1}^{n}\sum_{j=i+1}^{n} \mathcal{H}_{ij}$$

On page 152, paragraph 3, line 2, the reference to previous calculations on the interaction between water molecules, given as ref. 9, should be replaced by the additional reference 11: Hankins, D., Moskowitz, J. W., and Stillinger, F. H., *Chem. Phys. Lett.*, **4**, 527 (1970).

Erratum. The title of the communication by Mepham and Lane (*Nature*, **226**, 180; 1970) was given incorrectly on the contents page. It should read: "Adaptive significance of the sculptured exine of pollen".

Erratum. In Fig. 2 of the article "Preliminary Geological Interpretation of a New Hominid Site in the Lake Rudolf Basin" by A. K. Behrensmeyer (*Nature*, **226**, 225; 1970), the K–Ar date for the tuff in Koobi Fora should be 2·6 ± 0·3 m.y.

Erratum. In the article "Characterization of Ovine Hypothalamic Hypophysiotropic TSH-releasing Factor" by Roger Burgus, Thomas F. Dunn, Dominic Desiderio, Darrell N. Ward, Wylie Vale and Roger Guillemin (*Nature*, **226**, 321; 1970), corrections should be made to Tables 5 and 6. The first column of Tables 5 and 6 should read respectively:

Saline	Saline
Saline	5×10^{-9} g (X)
Saline	20×10^{-9} g (X)
Saline	80×10^{-9} g (X)
150×10^{-9} g (X)	T_3, saline
150×10^{-9} g (X)	T_3, 5×10^{-9} g (X)
150×10^{-9} g (X)	T_3, 20×10^{-9} g (X)
150×10^{-9} g (X)	T_3, 80×10^{-9} g (X)
	T_3, 1×10^{-6} g (X)

Erratum. The following corrections should be made in the article "Increase in Antiviral Activity of Polynucleotides by Thermal Activation" by E. de Clercq, R. D. Wells and T. C. Merigan (*Nature*, **226**, 364; 1970): The second sentence of the first paragraph should read "The thermal activating effect . . . was most marked with the alternating polyribonucleotides such as poly (A–U) and poly (I–C)". The second footnote in Table 1 should read "†Minimal Eagle's medium (MEM), *p*H 7·0–7·5 . . . ". In the paragraph following Table 1, the first sentence should read "Preincubation at 37° C, compared with 0° C, rendered all polynucleotides, including poly I·poly C, significantly more active in reducing virus plaque formation in human cells, when the incubation was carried out in MEM (Table 1)", and the sentence beginning on line 16 of that paragraph should read "Addition of 10^{-3} M EDTA following the 37° C incubation step or rapid cooling to 0° C (by immersion in solid CO_2–ethanol) did not reverse the activating effect . . .".

Erratum. The contents entry for the article by N. R. Blacklow and A. Z. Kapikian "Serological Studies with EB Virus in Infectious Lymphocytosis" (*Nature*, **226**, 647; 1970) should have been **Infectious lymphocytosis,** not **Infectious mononucleosis.** In the article itself, five lines from the end, read "these children" not "three children".

Erratum. An amendment should be made to the erratum (*Nature*, **226**, 782; 1970) referring to the article "Increase in Antiviral Activity of Polynucleotides by Thermal Activation" by E. de Clercq, R. D. Wells and T. C. Merigan (*Nature*, **226**, 364; 1970). The sentence beginning on line 16 of the paragraph following Table 1 should read "Addition of 10^{-3} M EDTA following the 37° C incubation step did reverse the activating effect whereas rapid cooling to 0° C did not".

Corrigendum. In the article "Netherlands: Stop and Go on the Nuclear Merry-go-round" (*Nature*, **226**, 1020; 1970), the figure given in the right-hand column of p. 1021, line 22, should be Dfl. 550,000,000, not Dfl. 550,000.

Erratum. The paper referred to as by E. P. Geiduschek *et al.* in the report of the RNA transcription symposium at Cold Spring Harbor (*Nature*, **226**, 1094; 1970) should be attributed to A. Cascino, S. Riva and E. P. Geiduschek.

Erratum. In the article "Solar UV Flash Spectrum 1400 Å–1960 Å" by G. E. Brueckner, J. F. Bartoe, K. R. Nicolas and R. Tousey (*Nature*, **226**, 1132; 1970), the following corrections should be made. In line 4 of paragraph 1, XUV should read "extreme ultraviolet"; the reference to Fig. 6 on line 57, p. 1134, should be to Fig. 5; column 3 of Table 2 should read as follows:

	Transition	
2p	$^3P_2$–2p′	$^3D_3$
	$^3P_2$–	$^3D_1$
	$^3P_2$–	$^3D_2$
	$^3P_1$–	$^3D_1$
	$^3P_1$–	$^3D_2$
	$^3P_0$–	$^3D_1$
2p	$^3P_2$–3s	$^1P_1$
	$^3P_1$–	$^1P_1$
	$^3P_0$–	$^1P_1$
2p	$^3P_2$–3s	$^3P_1$
	$^3P_1$–	$^3P_0$
	$^3P_1$–	$^3P_1$
	$^3P_2$–	$^3P_2$
	$^3P_0$–	$^3P_1$
	$^3P_1$–	$^3P_2$

Erratum. In the article "Advantages of an Antagonist" (*Nature*, **226**, 1199; 1970) two references were incorrectly cited. The correct citation for Obata *et al.* is *Exp. Brain Res.*, **4**, 43 (1967) and that attributed to Werman *et al.* (*Life Sci.*, **4** 2075; 1965) was actually due to Aprison and Werman.

Erratum. In the article "RNA-dependent DNA Polymerase in Virions of Rous Sarcoma Virus" by Howard M. Temin and Satoshi Mizutani (*Nature*, **226**, 1211; 1970), the third line of paragraph 4 should read "Tris-HCl buffer at *p*H 8·0, containing 0·33 mM EDTA and".

Printed in Great Britain by Fisher, Knight & Co. Ltd., St. Albans, and published by
Macmillan (Journals), Ltd. at 4 Little Essex Street, London, W.C.2.

Nature in North America: The *Nature* office in Washington DC has opened and contributors in the United States and Canada are invited to submit manuscripts for publication either to the address given below or to the present London office. The intention is that each office will be able to answer inquiries about all manuscripts and other matters. This is one of several steps by which it is hoped to provide a better service for readers and contributors.

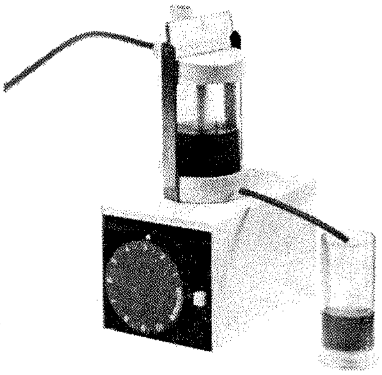
Rapid concentration and purification of proteins and other macromolecules

. . . molecular separation
. . . protein-free filtrates
. . . dialysis

Diaflo® MEMBRANE ULTRAFILTRATION

Installed in Amicon magnetically stirred Pressure Cells, DIAFLO Membranes concentrate dilute protein solutions ten to a thousand fold within short periods. Essentially complete removal of salts or other small molecules can be effected within a similar period of time by Diafiltration techniques.

DIAFLO Membranes are non-plugging and reusable. Each class of membranes has distinct chemical resistivities and physical characteristics. All membranes are non-denaturing and biologically inert.



AMICON ULTRAFILTRATION CELLS
will process biological solutions with volumes from 0,5 ml to 20 litres

Membranes retain molecules above line, pass those below line.

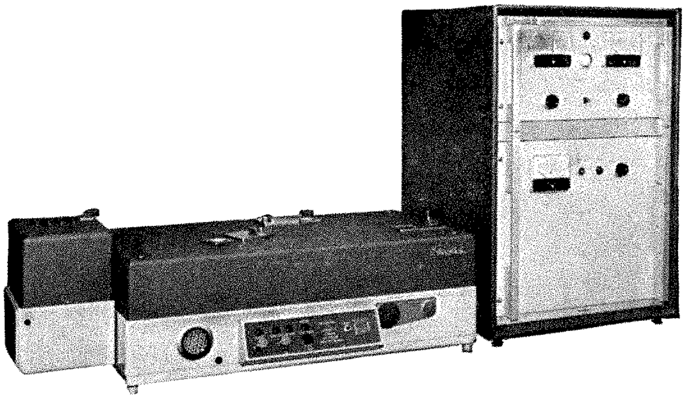
Precision Instruments

The POLARMATIC 62 Automatic Spectropolarimeter



NOW O.R.D + C.D

We are pleased to announce that a Circular Dichroism attachment has been designed by the National Physical Laboratory and will shortly be available for this outstanding spectropolarimeter. Like the Polarmatic itself, this new device will once again open up new thresholds in biological research.

A great deal of engineering development has enabled us to offer this attachment to both new and present users of the O.R.D. instrument. For full details write to Dept. N.

We now have capacity for aluminising certain types of mirrors, at short notice.

Long Shadow from Apollo

By now, the daily newspapers will tell how the saga of Apollo 13 has been finished. Whatever the outcome, the successful firing of a rocket engine in the early hours of Wednesday (GMT) seemed at the time a good augury only against the hazardous background of potential catastrophe. To be sure, it was lucky that the trouble with the oxygen tanks in the command module did not happen in still more alarming circumstances, after the fuel in the landing vehicle had been used up, for example. That would have been worse. As things turned out, it is also inevitable that there should have been heart searching about the events preceding the launching less than a week ago—the trouble with the fuel tanks and the sudden replacement of one pilot. None of this can conceal, however, the great courage with which those directly involved carried on with their work. Even if Apollo 13 missed the landing on the lunar highlands, it provided a moving and more public demonstration than ever of how people can face the prospect of sudden death in a seemly and modest fashion.

One of the striking features of the past days has been the sheer competence of the people who have been concerned, on the ground as well as in the sky. As always, NASA has put on a good show, and there is more to this than the mere capacity to keep a stiff upper lip or even to diminish real dangers. Of all the claims which have been made in the past several years that the exploration of space has brought unexpected benefits in unrelated fields, perhaps the most important is the least tangible—the way in which the organization functioned superbly in the course of the most daring exploits. A part of the secret has been that there have been enough men on hand to think of everything, or nearly everything. Another has been the logic of the planning. By themselves, even armies of design engineers could not have accomplished what the Apollo project has done in less than two years—since Mr James Webb unaccountably gave up his job as administrator, the hydrogen rockets of the second and third stages have been successfully brought into service, and the whole system of hardware for landing on the Moon has been tested and used to its full capacity on two occasions. For as long as people are concerned to do things for the first time, the conduct of Apollo will be a monument to the way in which pure reason can accelerate complicated technical developments. Nothing decided in the next few months should diminish the importance of this brilliant demonstration. Those who are inclined to complain that there has been an accident should, rather, wonder why it has not happened before.

What will happen next, in the next few months and in the decade which lies ahead ? The immediate future is in no doubt. It is unthinkable that the flight of Apollo 14, originally planned for the end of October, should continue without the kind of careful analysis of the past few days which followed the death of three astronauts by fire just three years ago.

Whatever the examination may reveal—and NASA has a good reputation for honest self-criticism—the outcome is likely to be a further attenuated sequence of journeys to the Moon. Most probably it will be 1971 before the next Saturn V rocket leaves the ground. Two things should be said. First, it is important that two journeys to the Moon have been successful, that the trouble with Apollo 13 has probably been the result of some statistical error and that there is no reason why the same equipment should not function well on some other occasion. But the way in which the great mass of material returned by Apollo 12 is still being filtered through the terrestrial laboratories should also be a comforting sign that there is no great need for hurry. If the purpose of these visits is to bring back a better understanding of the Moon, no serious damage will be done if the interval between successive flights is more like a year than the six months now allowed for.

The accident has come at an awkward time for NASA, with the budget for the year to the middle of 1971 still lying in the lap of Congress. Suffused with the confidence of two successful landings on the Moon, NASA has turned its attention to other projects—the space station in orbit about the Earth (with all kinds of astronomical telescopes to give it point) and the scheme for making a re-usable rocket or shuttle. The space station would take a good part of the effort in the year ahead, but the shuttle would remain more or less on the drawing boards—indeed, only the design of the engine would be carried this year to the point at which contracts could be placed. All this is part of the Nixon administration's strategy for the next decade—a somewhat humdrum preoccupation with two new aspects of the technology of space flight and some spectacular frosting on the cake to round it off—the grand tour of the outer planets on which automatic rockets could be sent in the later seventies. In the past few months, and with the success of the last two journeys to the Moon very much in mind, NASA has been pretending that possible grandeur has been postponed for the sake of a balanced budget. Now there may be a more sensitive appreciation of the staggering innovations of principle there will be in the design and development of the shuttle rocket. Is it really on the cards that such a device could be in service by the late seventies, and if so, what would it be for ? This is the kind of question likely now to be asked in Congress. Maybe NASA has an answer, but it ought to be better and more interesting than those given so far.

This may also be an occasion for yet another reconsideration of the objectives of the space programme, in the United States, the Soviet Union and the other nations from which rockets are being aimed at orbits around the Earth. It is no disrespect to the three brave men in Apollo 13 to recall that human intervention is still comparatively unproductive. The great skill which NASA has embodied in the Apollo programme is premature. Now that the technique has been learned, it would be foolish deliberately to forget it, which means that space flight should be continued on some sensible scale. Within the kind of budget to which NASA is becoming accustomed, however, there are much more urgent tasks than this. One of the disappointments of the new budget has been the postponement of some of the Earth satellites that could demonstrate the feasibility of useful arts—still better telecommunications and aircraft navigation chief among them. And where scientific exploration is concerned, it is still regrettably fair to say that the money thus spent is allocated not by the test of what will be best for science but with the extra and artificial constraint that rockets must somehow be involved. What NASA needs is a set of tangible goals in space technology and exploration, and a more open-ended programme of space travel.

The truth is that there is no great need for hurry. In the late fifties, after the Sputniks, there may have seemed good reason for an American demonstration of competence. This has now been done, and the seventies are, in any case, likely to be very different from the fifties. In a funny way, the United States space programme has become old-fashioned. There is no reason why it should be abandoned—indeed, the greatest danger now is that indifference or disillusion may make it hard to recruit enthusiasm (and money) for jobs that need badly to be done. There are also splendid opportunities, as Dr Thomas Paine is always saying, for making space research much more a vehicle for novel forms of international collaboration. But in circumstances like these, over-definite objectives such as the space station and the shuttle may be less valuable even as spurs to space travel than a more open-ended programme, with one step following deliberately on another. No harm would be done in making fuller use of the Saturn rocket before going on to fresh imponderables.

Passivity and Activism for Stockholders

SEVERAL universities in the United States are being assailed by students and others moving under the label "Campaign GM" to make a radical reappraisal of their attitudes towards their investments. GM means General Motors, one of the stocks widely favoured by those anxious to see that academic endowments are not too dangerously dependent on the ups and downs of the stock market. The objective of the student campaign is to persuade universities holding large amounts of General Motors stock to play a more active part than has been their custom until now in the management of the company and, in particular, to set up a committee of inquiry to assess the vigour of the corporation's attempts to produce cars which are safe and free from pollution, to add three directors to the board "who will insist that the board takes account of the many social consequences of its decisions" and also to amend the corporation's charter so as to prevent it "from engaging in conduct which is illegal or detrimental to the public health, safety and welfare". The campaign has already picked out the three extra directors it would like to appoint—one of them is Dr Rene Dubos of the Rockefeller University. Understandably enough, the management of General Motors plans to resist these proposals at the shareholders meeting on May 22, chiefly on the grounds that they are tantamount to intolerable restrictions on the management of the company. University administrators are finding it less easy to make up their minds, not least of all because it seems plain that a decision to intervene in the management of General Motors is likely to imply that more interest will have to be taken in other companies and their affairs. The fact that the University of Pennsylvania was the first of several universities now under pressure to agree that its 29,000 shares should be voted in the sense of the campaign's proposals is unlikely by itself to carry weight elsewhere, and it is only fair to expect that even if the university stockholders are unanimous, their total holding of rather less than a half per cent of General Motors stock will not be decisive. Nevertheless, the issues that have been raised are important and also interesting.

The first reaction of universities elsewhere will be envy at the way in which so many American universities seem to be provided with endowments, embarrassing or otherwise. Others will recall that many Oxbridge colleges have had and still have investments which consist of parcels of land which are sometimes managed with less concern for social values than many academics would have wished. The way in which the Commissioners of the Church of England used to be attacked for their ownership of brothels in London was in its way a more obvious anomaly than the case of General Motors—after all, the allegations of social irresponsibility against the manufacturers of automobiles are open to dispute even if the authors of Campaign GM think their validity is self-evident. For universities, however, the question is how and when decisions about investments should be tempered by an awareness of the uses to which the investment is put. The traditional view of university treasurers has been substantially that of Dr Nathan M. Pusey, the president of Harvard University, who said some years ago that "our purpose is just to invest in places which are selfishly good for Harvard—we do not use our money for social purposes". On the strict interpretation of the terms under which many bodies of trustees must function, universities have no alternative. Many trust deeds leave no room for trustees to do other than maximize the financial return on what they are able to invest. To say that the prospect of a high yield should be forgone because the company concerned is making products which are socially undesirable—armaments perhaps—may often be a kind of dereliction of duty. To be sure, it would often be hard to make such a charge effective so that trustees might be able to meet some particular objections without running into trouble. The more practical difficulty is that of asking the managers of large and diversified endowment funds to make decisions which are acceptable to faculty and students on all new investments. If ever there were a prescription for making sure that academic productivity was completely prevented by the length of faculty meetings, this is probably the one. A further difficulty, harder to avoid, is that the instincts which have helped to launch Campaign GM are as much concerned to undermine the power of big corporations as such as to make sure that General Motors manufactures different kinds of motor cars. There is, in other words, a danger that if the universities take the wishes of Campaign GM too seriously, they may well find themselves with no alternative but to lend their money to the banks, which would, no doubt, in turn pass it on to the big corporations.

In short, Campaign GM must not be thought of as a serious attempt to redirect the financial resources of industry but as a gesture by the universities towards the large corporations. As such, and particularly because the specific proposals which have been put up for the shareholders' meeting on May 22 are unlikely to succeed, there may be some virtue in letting the issue out into the open. To begin with, it will help to give universities in the United States a more accurate appreciation of their financial strength and weakness if there is now some public discussion of the character of their investment funds. Paradoxically, Campaign GM has come at a time when a great many private universities have been forced to recognize that costs are rising much faster than their endowment income. Gestures of self sacrifice, even if they consist merely of persuading General Motors to be less profitable by being more socially responsive, will have a certain heroism. The second benefit of this confrontation should be that universities will have to think out more clearly than they have done so far the ways in which companies can be made more socially responsive. In the long run, of course, seeking as Campaign GM does to impose restraints on corporate management is by no means the most effective way in which universities might influence the course of industrial events. Where the safety of motor cars is concerned, for example, universities could do valuable work by playing a more vigorous part in the attainment of protection for consumers by the development of technical standards of performance. This kind of activity is more logically a part of the philosophy of Campaign GM than the attempt to pack the board of directors with high-minded people. But, that said, it will be interesting to see how General Motors will respond to the demands now made on it.

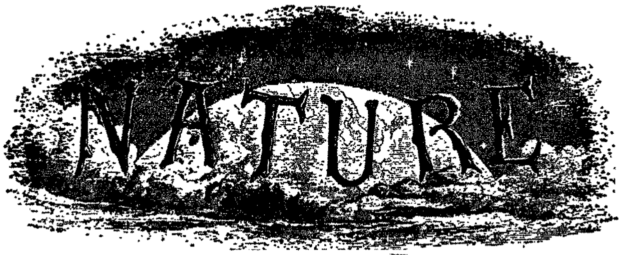
Mr Nader's Crusade

EVEN if some of Mr Ralph Nader's charges against the Food and Drug Administration are exaggerated and even biased, the report which his team has now published (page 205) deserves and will get close attention. Of the criticisms levelled at the Food and Drug Administration, the most damaging are those which argue that the administration is trying to do much with a staff which is too small and ill-provided. The more sensational parts of the report, such as that which retells one version of the story of how cyclamates came to be banned from the market in October last, are less reliable. Even now, six months later, it is hard to know who is right and who is wrong about cyclamates. Some evidence of the causation of bladder cancer by cyclamates has accumulated in studies with laboratory animals, but there is no knowing how the extrapolation from animals to human beings is to be accomplished. At the same time, the usefulness of cyclamates as means of sweetening food and drink without making people fat has been called into question and plainly further study would be necessary if, in the present climate of opinion, cyclamates were being introduced for the first time into foodstuffs. Mr Nader's team, in its criticism of the FDA, tends unfortunately to paint too sharp a picture of the disagreements between officials within the organization. It may be true that some officials had been pointing out for several years that cyclamates might be harmful, but it does not follow from anything that Mr Nader has said that the FDA was wrong in overriding this advice. Indeed, the most telling point of his team's criticism of the FDA on cyclamates is that in the end the ban was imposed on the narrow grounds provided by the Delaney amendment. Plainly it would have been better if the case for prohibition could have been more broadly based. The trouble is that then, as now, the case is not yet convincing.

The case history of the cyclamate ban is important, however, because it calls in question the capacity of the Food and Drug Administration to act vigilantly and quickly in the regulation of foodstuffs. The truth is that to provide a cast-iron demonstration that some substance, either a foodstuff or an additive, can be marketed safely is bound to be time consuming and expensive. Mr Nader's team assumes that the FDA should be able to carry out all the investigation needed to justify the inclusion of new materials in the safe list. There may be a case for holding this point of view, but if it were accepted, it would be necessary to increase the research strength of the FDA not merely by a factor of two or three but by an order of magnitude.

This is why one of the most disappointing features of the new report, the most recent in Mr Nader's programme to expose all the regulatory agencies to scrutiny, is that it has very little to say about the philosophy which should be adopted by organizations like this. In the past twenty years, the Food and Drug Administration has made a good name for itself by developing and enforcing standards of purity for food. More recently, it has plainly found it harder to keep up with the monitoring of innovation. The ambitious but well intended plan to drive off the pharmacy shelves not merely drugs which are dangerous but those which are in some sense or another unnecessary is having to be farmed out to committees such as that organized by the National Research Council, a procedure which exposes both parties to the bargain to some unnecessary hazards. The difficulty is that any other course would require a Food and Drug Administration which is not merely able to keep pace with the manufacturers but which can also anticipate their innovations.

100 Years Ago



The distance across the Channel on the line chosen is about 22 miles. The tube as proposed is large enough for the passage of carriages of the present ordinary construction, and to avoid the objections to the use of locomotives in a tube of so great a length, and the nuisance which would be thereby created, and taking advantage of the perfect circular form which the mechanical operation of turning, facing, &c., will insure, it is proposed to work the traffic by pneumatic pressure. The air will be exhausted on one side of the train and forced in on the other, and so the required difference of pressure will be given for carrying the train through at any determined speed. Powerful steam-engines, with the necessary apparatus for exhausting and forcing the air into the tube, will be erected on shore at each end; and supposing one tube only to exist, the traffic will be worked alternately in each direction.

It has been found by calculation, that, for moving a large amount of tonnage and a great number of passengers, the most economical arrangement will be to send combined goods and passenger trains through the tube at 20 miles an hour, with occasional express trains at 30 miles an hour. Thus, an ordinary or slow train would occupy about 66 minutes in the transit, and a quick or express train about 45 minutes. In this way the tube, if fully worked, would permit the passage of 16 ordinary slow trains (8 each way), and 6 express trains (3 each way), each conveying both goods and passengers. About 10,000 tons of goods per day, or upwards of 3,000,000 per annum, and 5,000 passengers, or nearly 2,000,000 per annum, might be taken through, or a less amount of goods and a larger number of passengers, or *vice versâ*, if circumstances rendered other proportions necessary or desirable.

From a report in Nature, 1, 632, *April* 21, 1870, *of an Anglo-French scheme for constructing a Channel Tunnel.*

OLD WORLD

SALARIES

Pay Rise for Dons

by our Education Correspondent

THE latest recommendations of Mr Aubrey Jones's Prices and Incomes Board on university teachers' pay are unlikely to provoke the howls of indignation and the resignations that greeted the first report. An across-the-board rise of 9 per cent, backdated to October 1, 1969, has been recommended (*Standing Reference on the Pay of University Teachers*, Cmnd 4334, HMSO, 6*s*). It is true that this goes little more than half-way towards meeting the claim put in by the Association of University Teachers last December, but at least the stumbling block of the previous report—that students should have some say in assessing the teaching ability of staff—has been tactfully dropped.

The award will add about £9 million to the total salary bill, and will give assistant lecturers an increase of about £112. The average professor will find himself better off to the tune of about £420 a year. The Association of University Teachers (AUT) asked for increases ranging from 11 per cent for junior lecturers to 15 per cent for professors, and Mr Laurie Sapper, the AUT's general secretary, said that although the association is disappointed that its claim has not been met in full, it is only an interim award and the offer which will be made in October this year may be nearer the level asked for.

When the AUT put in its claim last December, it argued for greater increases at the top end than at the bottom of the salary scale, because shortage of finance has reduced the ratio of senior to junior teachers and caused career prospects to deteriorate. This argument cut no ice with Mr Jones's committee, which suggests in its report that career prospects would be improved much more by removing the UGC's fixed ratio of senior teachers to total number of staff. This proposal, which is supported by the AUT, seems to have been left out of the list of recommendations given at the end of the report, and even if it is accepted by the government it may not make any immediate difference to staff ratios. In most departments, except medicine, the proportion of senior staff is in any case well below the figure recommended by the UGC.

University teachers have always been bitterly opposed to government regulation of their salaries through Mr Jones's committee, and Mr Sapper said that the AUT "rejects completely" the proposal that the Prices and Incomes Board should be involved in further negotiations about university salaries. New machinery for negotiating salaries, which involves direct talks between the AUT and university authorities, is being studied by the Secretary of State for Education at the moment, but the Prices and Incomes Board report suggests that such machinery should not be brought into operation until 1971. A study of university teachers' pay commissioned by the Prices and Incomes Board, and being carried out by the Higher Education Research Unit at the London School of Economics, should be completed in March 1971, and until that time Mr Jones's committee wants to stay in the saddle. But at least British dons are not alone in their opposition to current methods of salary negotiation. Australian research scientists were recently awarded salary increases of as little as 3·5 per cent by the Commonwealth Arbitration Commission (*Nature*, **226**, 99; 1970), a decision which sparked off widespread criticism of the arbitration system and prompted the scientists to commission a job evaluation survey by a firm of management consultants. Lower grades of research scientists in Australian laboratories earn a minimum of about £2,900, compared with £1,240 for assistant lecturers in Britain.

COMPUTER POLICY

Hard Sell for Software

AN amazing case of duplication of effort in government departments was described at last week's hearing of the Select Committee on Science and Technology investigation into the British computer industry. Mr Kenneth Barnes, managing director of Systems Programming Ltd, and self-appointed spokesman for Britain's £10 million software industry, alleged that the software for each of twenty-three payroll systems for use on ICL 1900 series machines in government departments was developed separately, a revelation which Mr Eric Lubbock described as "shocking". According to Mr Barnes, the matter is already attracting the attention of the Civil Service Department, but there is no mechanism in government departments to make known the programs which have been developed for 1900 series machines.

At present much of the software work for government departments is carried out internally, although the Civil Service Department seems to be reassessing this policy. Naturally, Mr Barnes wanted to see more of the software work put out to tender, and this view was supported by Mr Saul Steinberg, the controversial chairman of Leasco Data Processing Equipment Corporation, who was the chief witness at this week's hearing. Citing experience in the United States, where there is almost no software work carried out internally by government departments, Mr Steinberg said that the competition for contracts is good both for government and for the software industry. In the United States, Mr Steinberg said, secrecy is no obstacle and even the most sensitive contracts in national defence are given to private companies.

Pressed to give his opinion of the prospects for International Computers Ltd, the British computer manufacturer, Mr Steinberg said that ICL is in difficulties because it is marketing two unlike computer systems —System 4 and the 1900 series. This is something which even IBM would certainly never undertake. In any case, the British market is too small; a market the size of Europe is the minimum for a manufacturer such as ICL. But chauvinistic feelings are bound to make impossible the strategy of merging what is left of the European computer industry in one move. What ICL should do to break into foreign markets is merge with one international company, and build up from there. The government could help by giving ICL a contract for the development of machines compatible with both System 4 and the 1900 series, if that were a feasible task to attempt.

But both hearings concentrated on the British software industry, which Mr Barnes expects to grow by at least 30 per cent per annum up to 1974. The invasion of the British software market which Mr Barnes was prophesying two years ago has not come about to the extent which was feared, Mr Barnes said, but nevertheless it is crucial that the British software industry take action to build up its muscles. Compared with the largest American software houses with up to 3,000 employees, British firms are small fry with staffs of a few hundred which are not equipped to tackle large-scale systems. The industry must take steps to consolidate itself, but mergers will be difficult to achieve bearing in mind that the chief assets of the companies are their staffs of independently minded individuals. According to Mr Barnes, the Industrial Reorganization Corporation has been considering a merger of three software houses, but it was obvious that nothing would come of the idea. One approach, Mr Barnes agreed, would be to merge software houses with management consultants. This should produce organizations capable of integrating computer systems with management more effectively—both witnesses recognized that this is an important aspect of software work which needs more attention.

COMPUTERS

German Companies Join Forces

THE proposed merger of the computing interests of Siemens and AEG-Telefunken, the two West German companies, is expected to bring a breath of fresh air to the discussions on a giant European computer which have been labouring somewhat during the past months. Although Siemens is already the second largest European owned company in Europe, after International Computers Ltd, the benefits of a more unified West German approach to European collaboration are felt to be more than adequate compensation to other European computer firms for any increased rivalry that may accrue from the proposed merger.

The West German Government has been stepping up dramatically its investment in the national computer industry, partly to counter growing pressures from American companies. Government aid is 90 per cent up this year compared with 1969, and is expected to reach £34 million over a five-year period. The importance attached to the industry became clear when Dr Stoltenberg, the Minister of Science in Dr Kiesinger's government, created a new department to coordinate government activity in this area.

The chief impact of the proposed merger will be in the large computer market, in which AEG-Telefunken is strongest.

There is little indication of any intention to merge the interests of the two companies in smaller computers, which may help to account for the cheerful view of ICL, whose specialities lie outside the large computer range. But ICL is naturally aware of the inroads an expanding German industry could make into its own buoyant markets in Eastern Europe and France.

Technical incompatibility between the machines of ICL and Siemens has been held by some West German sources to be partly responsible for dulling the talks on the Aigrain proposals for a giant European computer. But there is renewed hope now that the European talks will gain some new momentum. Certainly the West German company will feel itself in a stronger negotiating position.

TECHNOLOGY

Cold Line Diplomacy

"TECHNOLOGY has now abolished 'foreign affairs'," remarked Mr Wedgwood Benn, on the eve of his 10-day official visit (April 14–24) to the United States. The volume and complexity of material to be exchanged between countries today cannot be squeezed through such a narrow pipeline—like pouring water through a bootlace, as has been said in a similar context. The traditional procedures of communication between governments are very cumbersome. "At present it takes three months to write a letter to a minister of another country—and three months to get an answer back. What we want today is not hot lines but more cold lines. . . ."

In pursuit of this idea the Minister of Technology has proposed an informal bi-monthly lunch club for Euro-technology ministers, alternately meeting in Paris, Bonn and London. Last week's London visit by M. Ortoli, the French science minister, and Germany's deputy research minister, Herr von Dohnanyi (at the British minister's invitation), was something of a trial run. They were here to coordinate Europe's preliminary response to NASA's recent invitation to participate in the American space programme for the 70s (see *Nature*, **226**, 2; 1970). Mr Benn does not believe Europe can afford to delay declaring an interest until the midsummer European Space Conference. On the other hand, further technical and financial studies of the proposal are still needed. Perhaps Mr Benn on his present visit can set up a cold line between Millbank and the office of NASA's chief, Dr T. Paine.

POLLUTION

Less Oil on Troubled Waters

STERNER government measures to restrict the discharge of persistent oils into the sea can be expected soon. The Board of Trade announced last week that a bill to be introduced into Parliament as soon as possible will greatly extend existing restrictions, and will include an absolute ban on the discharge of any persistent oils —crude, fuel, heavy diesel and lubricating oils—from the cargo spaces of tankers within fifty miles of land. This will reinforce the present ban on the discharge of all types of oil within United Kingdom territorial waters, which usually means three miles from land.

The bill is designed to modify the Oil in Navigable Waters Acts of 1955 and 1963, which are being brought into line with the International Convention for the Prevention of Pollution of the Sea by Oil as amended in October 1969. This convention was first agreed in 1954 by the member countries of the Assembly of the Inter-Governmental Maritime Consultative Organization (IMCO), a specialized agency of the United Nations. The latest amendment prohibits the discharge of persistent oils into the whole of the North Sea, the English Channel, and more than 1,600 miles westward across the Atlantic Ocean and south to Finisterre. Furthermore, new ships of 20,000 gross registered tons or more may not discharge these oils anywhere at sea. Britain is one of the first countries to take action on this amendment, which cannot come into force until it has been adopted by two-thirds of the contracting governments. The convention is now in force as it was amended in 1962; in that form it has been accepted by forty-one countries.

The full scope of the legislation to be introduced in Britain will not be known until the bill is published, but there will be measures to facilitate enforcement of the proposed ban by requiring tankers to keep more detailed records of cargo movements and disposal of oil residues. The fines imposed for unlawful discharge of oil within British waters and by British ships in other waters are also under review, and tougher penalties could form part of the new legislation. At present the fine is £1,000 on summary conviction, with no limit on fines imposed if conviction is on indictment.

The Board of Trade reports that last year there were eighty prosecutions for unlawful discharges of oil, resulting in seventy-seven convictions, compared with sixty-two in 1968 and fifty-nine in 1967. Three of the seventy-seven of last year's convictions were for discharges outside harbours, and the rest for offences within the jurisdiction of harbour authorities. Fines imposed totalled £17,550, from which five awards amounting to £792 were made towards the cost of removing the oil pollution.

ENVIRONMENT

Not Just Talk

CONSERVATION is now catching on fast enough for good advice to be out of date before it is given. The Countryside in 1970 Committee has unwittingly confirmed the encouraging growth of activity by publishing this week a report on conservation policy whose proposals for administrative reform have mostly been put into practice already. Its chief recommendation, that responsibility for the environment should be centralized in the ministers who deal with local government and planning, has even fallen short of the government's action in creating a single Ministry of Local Government and Regional Planning under Mr Anthony Crosland, which occurred after an *ad hoc* group had prepared the report (*Governmental Responsibility for the Environment*, available from 19 Belgrave Square, London SW1).

The group, under the chairmanship of Lord Hurcomb and including Sir John Winnifrith, Mr Max Nicholson and Mr Walter Lane, also recommends that the relevant ministers appoint a conservation adviser, a demand that has been at least partly satisfied by a central scientific unit set up by Mr Crosland to look after the government's pollution research. The unit is headed by Dr Martin Holdgate, whose status is at the level desired by the Countryside in 1970 Committee, for he will be directly responsible to Mr Crosland and his unit will work closely with the government's chief scientific adviser, Sir Solly Zuckerman. A further bonus that the committee did not call for is the Royal Commission on pollution that was announced at the same time as the scientific unit.

Among the voluntary bodies dealing with conservation, the report says, there may be a confusing degree of overlap, but the coordination that it wanted has arrived in the shape of the joint Committee for Environmental Conservation, which was being planned while Lord Hurcomb's group was working. This committee is now bringing the voluntary associations together in studies of pollution, road transport and coastal management, and also intends to carry out the second function wished on it by the report of confronting the government with recommendations when it feels a collective voice would be useful.

Some of the advice of the *ad hoc* group remains to be taken, notably at a local level, where it would like to see more strength given to the County Countryside Committees that were created, without legislative backing, as a result of the second Countryside in 1970 Conference in 1965. These groups, the report argues, are performing splendidly by providing a focus for environmental responsibility that would otherwise be dispersed among too many organs of local government, and there should be more of them. Because the future of local government is not clear, while the Redcliffe-Maud reforms are being pondered, the report makes no specific demands of local authorities but urges that, when they are reorganized, they should be made to "have regard to the desirability of conserving the natural beauty and amenity of the countryside", as was laid down by the 1968 Countryside Act. Elsewhere, however, the Countryside in 1970 Committee will have little to do but wait and see how far its ideas are followed in the spirit as well as the letter.

LIBRARIES

Bloomsbury for Books

by our Planning Correspondent

THE announcement in the House of Commons last week by Mr Short, Secretary of State for Education and Science, that the British Museum Library is, after all, likely to be rehoused on a site facing its present one in Bloomsbury has been welcomed all round, and particularly by the museum trustees who through years of frustration have stoically maintained that the area on the south side of Great Russell Street was the only practical site worth expanding onto. Mr Short also said that the government has accepted in principle the chief recommendation of the Dainton report on National Libraries, published last year, that a national libraries authority should be established to administer the museum library, the National Reference Library of Science and Invention (at present part of the British Museum Library), the National Lending Library, the National Central Library, and the British National Bibliography. The government, he said, was considering the structure and responsibilities of such an organization and it plans to issue a White Paper after it has had further consultations.

The suitability of the Bloomsbury site was first officially established in 1962 when the then Minister of Public Building and Works, Mr Geoffrey Rippon, appointed architects to prepare a design. The site was also favoured by the Dainton Committee, in spite of an earlier rejection of it by the government in 1967 on the grounds that it would have meant the demolition of a large number of houses in an area with a housing shortage. Mr Short now says, however, that it may be possible to rebuild the museum library and house the National Reference Library of Science and Invention as well, on a much smaller site than was originally planned because of recent technical developments in the storage of books and other library material. This would mean that fewer houses would have to be pulled down, and the whole of the west side of Bloomsbury Square would be preserved. This decision should help to calm both the preservationists and the Camden Borough Council, who have been the most vehement opponents of the original scheme to rehouse the museum library.

An important implication of the government's change of mind, and one that all scientists and librarians will welcome, is that it puts the future of the present National Reference Library on a more secure footing. Denied the site on the South Bank, and with its valuable stock scattered over London in several places, the library cannot offer the public the same level of service as if it were functioning in one central building and constituted, with the British Museum library proper, a National Reference Library in every sense. An added advantage of the Bloomsbury site for such a library is its proximity to the Patent Office, and to the University and other scholarly library collections in central London.

BRITISH MUSEUM

Falling Star Cast

MOON dust may have its devotees and tektites their fanciers, but neither form of extraterrestrial matter can compete with the fascination of meteorites. Last week the British Museum (Natural History) opened a new exhibition which at last does justice to what must be the most comprehensive collection of cosmic debris in the world.

Dominating the new pavilion like the Kaaba at Mecca is the squat, 3½ ton mass of the Cranbourne meteorite, coddled in an atmosphere of dry nitrogen lest its lawrencite corrode to rust. Illuminated glass-fronted niches on either side of the darkened chamber hold examples of the irons, stones and stony–iron meteorites. In a well at the centre lies a model of the swarm of meteorite craters at Henbury in Central Australia. The elegant design and exposition of the pavilion stand in sharp contrast to the faded Victorian glories of the mineral gallery whose long aisle the visitor has to walk to reach it.

The museum's collection began with a fragment of the meteorite which was discovered by P. S. Pallas in Krasnojarsk in 1775 and presented by the Academy of Sciences at St Petersburg. Since then the museum has acquired specimens from some 1,215 of the 2,127 known falls. The museum's catalogue of meteorites falls, the third edition of which has recently been completed by Dr Max H. Hey, is recognized on an international basis and serves, among other things, in directing people who require samples of particular falls to the museums that have most to spare. For those who have despaired of going to catch a falling star, the meteorite pavilion at least provides the consolation of being able to stand surrounded by part of the leftovers of the primitive solar system.

GOVERNMENT RESEARCH

Will BRDC Work?

THE latest attack on the green paper on industrial research and development in government laboratories has come from the Institution of Professional Civil Servants, which represents many of the staff in the organizations likely to be affected by the proposals if they go through. At the same time the Minister of Technology, Mr Anthony Wedgwood Benn, from whose department the proposals originated, has been defending the green paper to his critics on the House of Commons Select Committee on Science and Technology.

Much of the criticism is that the green paper is not sufficiently specific in its outline of the plan to form a British Research and Development Corporation out of what is left of the Atomic Energy Authority, the research and development laboratories of the Ministry of Technology which are undertaking civil work, and the National Research Development Corporation. This lack of detail is something which Mr Benn said was deliberate, to provoke discussion of the green paper, and he said that some of the proposals will be modified in the light of what has already been said.

But the essence of the IPCS criticism is the timescale which is envisaged for the setting up of BRDC. By 1975 it is intended that the corporation be able to support itself, earning one-third of its income from industry and the remainder from government sources. On this point the deputy general secretary of IPCS, Mr John Lyons, says that if the government sticks to the five-year period for generating one-third of the income of BRDC, this is "tantamount to an intention to create redundancy by taking away the income—if that is the case we will strenuously oppose the BRDC concept". The IPCS attitude is that a target contribution from industry of 15 to 20 per cent over a much longer period would be more realistic.

Mr Benn's approach to this point at the meeting of the Select Committee is that the target contribution from industry is not likely to be as difficult to achieve as people imagine. Although the gross annual cost of the organizations which would make up BRDC is currently estimated at £70 million, Mr Benn said that by 1975 this figure will be down to £60 million. The organizations already earn £10 million from industry, including £1 million for irradiation services in the Dounreay reactor and £1·8 million for the sale of electricity from prototype reactors. But if people fail to attract contract work from industry, Mr Benn said, then he would have to ask whether these people should be kept on. Despite this explanation, however, it is clear that the estimate of the industrial contribution to the running of BRDC is a major stumbling block to acceptance of the proposals. Many people would like to have seen a market survey, but this was ruled out by Mr Benn on the grounds that a market survey is something which is carried out when one is starting from scratch, whereas in this case he is dealing with established organizations.

- Mr Lyons of IPCS also criticizes the assumption that the Atomic Energy Authority has now fulfilled its purposes, a tenet that is taken as one of the justifications for BRDC.

IPCS believes that the directors of the organizations in BRDC should be free to develop their establishments within the framework of general policy, that moves to introduce a split between civil and defence work should be resisted, and that the finances of BRDC should be worked out on a long-term basis, preferably five years ahead or more.

Whether or not the IPCS supports the proposals in the green paper, the institution says, depends on the attitude of Mr Benn to these questions. For the moment, it reserves its decision.

Parliament in Britain

Euthanasia

THE campaign to legalize euthanasia seems to have met its end. The latest attempt was cut short when Dr Hugh Gray failed to bring in his Voluntary Euthanasia Bill. Dr Gray's bill sought to give every individual the choice between life and death if he ever became the victim of an incurable illness. The choice at the moment, he said, rests with the doctor, and although many would not seek to prolong life in hopeless cases there are some to whom life has an absolute value and who believe that it should not be taken away even when the patient is reduced to a living organic shell. Dr Gray argued that such a situation infringes individual liberty. The bill sought to give legal status to a declaration, either for or against euthanasia, which every individual could sign and which would be kept with his medical records.

Mr Norman St John-Stevas, who opposed the application to introduce the bill, pointed out that its intentions would contravene the moral and religious code that guides the majority of people in the Christian world, because it would allow one person to kill another. A doctor, he said, is under a duty to preserve life, but that does not necessarily mean that he must prolong the act of dying.

The application to bring in the bill was defeated overwhelmingly—MPs did not even bother to vote, but just shouted "No". Four euthanasia bills have now come before Parliament, and all have been heavily defeated. (Debate, April 7.)

Higher Education

THE growing interest among MPs in higher education was in evidence last week when Mr Short and his junior ministers answered questions. The much-discussed green paper on education in the 1970s, which may partly be responsible for the interest, should be published in the early summer, Mr Short announced, and it seems that many of his colleagues are expecting it to appear in May.

One of the main considerations is the number of places in higher education which will be available in 1980, but when asked by Mr Christopher Ward whether it is government policy to provide university places for 60 per cent of those qualified in the late 1970s, Mr Gerald Fowler refused to be drawn. That, he said, is one of the matters that will have to be decided in the course of this year. One point to emerge from a later question is that the government has no intention of establishing comprehensive universities, which would incorporate all institutions of higher education. When asked by Mr Boyd-Carpenter whether the government intends to continue selecting students by ability and aptitude at the age of 18, however, Mr Short replied that he hopes that universities will become increasingly comprehensive both in the structure of the student body and in the content of the courses, providing both degree-level and other courses. But such changes cannot be imposed from the outside. The notion of comprehensive universities has been widely canvassed both by the National Union of Students and by the Association of University Teachers.

Mr Fowler also announced that teachers, employers and other interested bodies are being consulted on the possibility of raising standards of entry to colleges of education. (Written and oral answers, April 9.)

NEW WORLD

Mr Ralph Nader and Pure Food

MR RALPH NADER, the scourge of Detroit, last week turned his attention to the Food and Drug Administration. His organization, the Center for Study of Responsive Law, published the draft of a book by James S. Turner called *The Chemical Feast* (available in mimeograph at $10) which seems well calculated to keep the new Commissioner of the Food and Drug Administration, Dr Charles C. Edwards, awake at night and, at the least, to burn the ears of Dr Herbert L. Ley, the commissioner who left his job last December. Mr Nader's introduction to the report, which is necessarily as objective as its thorough documentation would imply, directs mordant scorn not merely at the Food and Drug Administration for its "failure to ensure safe, pure and nutritious food in the world's largest bread basket" but also at the food manufacturing industry "for manipulating the content of food products as dictated by corporate greed and irresponsibility". There are nevertheless enough well directed charges in Mr Nader's document to stir a pot which is already boiling vigorously enough.

The tenor of the new study is embodied in the view that "making food appear what it is not is an integral part of the $100 billion food industry. The deception ranges from the surface packaging to the integrity of the food products' quality to the very shaping of food tastes". Techniques, Mr Nader says, amount to "nutritional deception" as in the way that "enriched white flour" is flour from which most nutrients have been removed, and the way in which additives of various kinds conceal "the rapid increase of fat content in frankfurters, their decrease in meat protein and the substandard quality of the meat". One result, he says, is that nutritional standards in the United States are declining, but the Food and Drug Administration, which should be in charge, has "failed to close out the options for corporate cost reduction and camouflage" and has in the process become "an official sponsor of processing and marketing practices that transformed the defrauding of consumers into a competitive advantage".

Mr Turner's text fills out this theme. He points out that "there has been almost no increase in the life expectancy of Americans" since the beginning of the sixties and that "black American men actually die younger than they did in 1959". The United States is no longer best in the infant mortality league table, while a study carried out by the *Journal of Nutrition Education* and reported last year (*J. Nutrit. Ed.*, **1**, 39; 1969) had shown that "dietary habits of the American public have become worse, especially since 1960". But the FDA has found "its meagre but well intended efforts" stifled by the interests of the food industry and is unable to "exert any meaningful influence on behalf of the food consuming public".

The Chemical Feast begins with cyclamates and has a number of novel charges to make, chiefly on the basis of internal memoranda of the FDA. According to Mr Turner, the FDA's first official dealings with cyclamates were in January 1950, when it allowed the Abbott Laboratories to market cyclamates as tablets for use by diabetics and others even though one of its officials considered the supporting evidence to be "an illustration of how an experiment should not be conducted". The official, said to have been Dr A. J. Lehman, asked that Abbott Laboratories should be told that "it is on the basis of our own work that recommendations are being made to permit this application to become effective". The Nader document goes on to say that the data on which the FDA relied in 1950 showed abnormally high incidences of cancer among the experimental animals and that "combining these suggestions of cancer with the shoddiness of Abbott's tests should have clearly indicated that more tests of cyclamates were needed" but that "this was the first of many danger signals about cyclamates which the FDA ignored".

The new report goes on to say that further warnings about cyclamates came from the Food Nutrition Board of the National Academy of Sciences in 1954, 1955, 1962 and 1968, and quotes from the statement in 1962 the view that considerations of public welfare preclude "the uncontrolled distribution of foodstuffs containing cyclamates". Mr Nader's team goes on to complain that the FDA never "effectively circulated" recommendations about the maximum daily intake of cyclamates put forward by the National Academy of Sciences' committee in November 1968 and goes on to say that the FDA put cyclamates on the list of food additives "generally recognized as safe" without adequate testing, but with the result that their use by the public could not afterwards be controlled. One of the charges against the FDA is that it has no systematic procedure for assessing the safety of compounds once these have been included on the GRAS list. The report also complains that the FDA did not re-examine its information about substances on this list after the amendment in 1958 to the Food, Drug and Cosmetic Act (the Delaney amendment) which requires that any additive should be held unsafe if it can be shown to cause cancer in men or animals.

The report goes on to say that the FDA ignored "scientific evidence indicating the dangers of cyclamates", as, for example, the suggestion that cyclamates are transformed into cyclohexylamine in the digestive tract of many people, the report in March 1968 by Dr Jacqueline Verrett of the FDA of a "firm relationship between cyclamates injected into chicken's eggs and deformities of embryos taken from the eggs", and the discovery, circulated within the FDA by Dr Martin Legator, that N-hydroxyl cyclohexylamine had been isolated from human prisoners given cyclamates. The study goes on to say that the commissioner of the FDA, then Dr Herbert Ley, ignored "at least ten other danger signals" in the period up to December 1968, including evidence of interference with anticoagulant therapy, unexplained liver damage, intestinal trouble and interference with drug action. The report also says that commercially available cyclamate contains "the dangerous and untested chemical cyclohexylamine" and that feeding tests had also shown that cyclamates "have limited effectiveness for weight control even under controlled dietary conditions". One of the most damaging passages in the report is the assertion that Dr Herbert Ley responded to a recitation of these points on December 12, 1968, by issuing a statement that although "totally unrestricted use of cyclamates would not be warranted", there "was little in the then widespread general use of cyclamates to be concerned about". The Nader study discounts the value of the report of the committee of the National Academy of Sciences set up specifically to study cyclamates and on which Dr Ley's public statement had been based by quoting from an internal memorandum in which two FDA officials describe that study as "a largely uncritical review of the available material".

The line of argument on cyclamates in the Nader study is that the staff of the FDA had accumulated enough evidence about the toxicity and teratology of cyclamates to justify their banning on more general grounds than those of the Delaney amendment on which cyclamates were removed from the GRAS list in October 1969. The study indeed complains that the Secretary of the Department of Health, Education and Welfare, Mr Robert A. Finch, misunderstands the Delaney amendment and its purposes, does not accept the notion that additives should be shown to be safe before being put on the market, underestimates the "growing scientific concern" about environmental chemicals and discounts "the protection of every scientist's right to communicate his findings to his fellow scientists and the general public".

The attack on the FDA includes the assertion that the narrow grounds on which cyclamates were eventually banned had meant that "the decision has easily been eroded by special interests". It would have been better, the argument goes, for Mr Finch to have asked manufacturers to demonstrate the safety of their products once doubt had been cast on them. The report says that "it was cynically irresponsible" of Mr Finch to retreat from the full scale ban, due to have become effective on February 1, 1970, by allowing first that foods containing cyclamates might be sold up until September 1, 1970, and then to suggest (on November 20, 1969) that foods (but not drinks) containing cyclamates might be sold so long as they were labelled. The Nader study goes on to suggest that the National Academy of Sciences committee on artificial sweeteners was not told of the concern within the FDA about cyclamates until 1969, that the advisory committee which drew attention on November 18, 1969, to the medical benefits of cyclamates did not consider evidence that these materials are ineffectual and that the Surgeon-General of the United States "has continued to participate in misleading the public and the scientific community" by concealing what he knew about the incidence of bladder cancer at low dosage in an article to which he contributed (*Science*, February 20, 1970). In summary, the Nader study says that the "cyclamate case establishes that the FDA has been less than diligent in applying the food protection laws. The Nader team is particularly cross that Mr Finch "never mentioned evidence that birth defects and genetic damage which were related to cyclamate in tests on laboratory animals are a more serious danger than cancer". For Mr Nader's team, the cyclamate decision must be viewed as the beginning, not the end, of public concern about chemicals in the food supply.

Although one of the most tangible parts of the attack on the FDA, the tale of the cyclamates is only a part of what the Nader team has to say. It complains, for example, that the FDA has been more anxious to root out food cranks and those who profit from them than to build up a capacity to keep a continuing watch on the practices of the food industry. It says that the FDA has cravenly capitulated to the demands by cola drink manufacturers that they should not be required to mention caffeine on their labels, complains that the FDA is wrong to insist that vitamin preparations should be labelled so as to indicate that "there is no scientific basis for recommending routine use of dietary supplements" and says that the FDA has been weak in promulgating standards for orange juice.

In general, the Nader study says, the FDA minimizes "the hazards of the chemical environment", denies the existence of under-nutrition, pays little attention to the risk of food poisoning from new methods of food manufacture and distribution and ignores research on the causes of heart disease and stroke.

Why should this be? The Nader team turns its attention to the food industry, now "moving towards monopoly". Advertising costs money as does the practice, attributed by the Nader study to the Campbell's soup manufacturers, of maintaining a collection of antique soup tureens "to counteract the bad image" produced when Andy Warhol showed his first pop art picture of a soup can. The Nader team says that the "purposeful and economically motivated pollution of baby foods by their manufacturers should dispel all beliefs in food industry self-regulation" and goes on to discuss the controversy about monosodium glutamate in baby food, in which the food industry "distorts or dismisses the warnings of responsible scientific critics against these components". The trouble, the study concludes, is that the FDA cannot distinguish between the interests of consumers and of manufacturers.

In a chapter on potentially mutagenic materials, especially pesticides, the report complains that the FDA has been arbitrary in its compilation of the GRAS list and that "more incredible even than this chemical by chemical deception practised by FDA officials was the agency's total acquiescence in industry's interpretation of the law". In practice, the report says, the FDA does not test additives when approving their safe use but relies on work done by others, often the manufacturers, and complains that it is muddled on questions such as the safe use of packaging materials.

One of the most serious charges against the FDA in the Nader document is that an internal study of the FDA's operations by Dr Maurice D. Kinslow in August 1969 was an "exercise in public relations" stimulated by the Nader study of the FDA and "designed to win public sympathy for an under-funded, under-staffed but honest regulatory agency harassed by Congress". One of the points in the Nader report which is likely to stimulate continued controversy is the charge that the FDA is scientifically less competent than it should be, and the document finds fault with the Kinslow report for minimizing the importance of scientific research within the FDA.

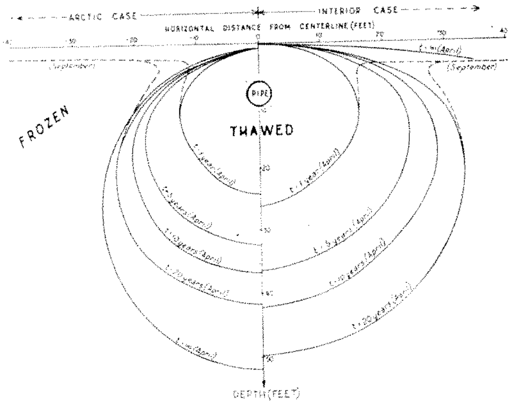
Further Delay for Alaskan Pipeline

THE difficulties of exploiting the oil fields on the North Slope of Alaska seem to be increasing. Although the scheme to build a pipeline across Alaska, between Prudhoe Bay on the North Slope, and Valdez on the Pacific coast of Alaska, should by now have been under way, it now looks as if there will be yet another public inquiry which will almost certainly mean a year's postponement. Indeed, the Conservation Subcommittee of the House of Representatives has written to the Secretary of the Interior, Mr Walter Hickel, asking for a postponement until the consequences of building the pipeline can be more accurately anticipated. At the same time, the second voyage of the oil tanker Manhattan through the North West Passage, which began last week, has coincided with the introduction of a bill into the Canadian Parliament in Ottawa that claims on behalf of the Canadian Government jurisdiction over a tract of sea running 100 nautical miles north of the Canadian Arctic coast, at least where threats to the environment (such as oil tankers) are concerned. Although the US State Department reacted smartly by saying that such an extension of maritime jurisdiction would be unacceptable, the proposed bill is likely to serve as a focus for Canadian discontent about the risk of oil pollution in the Arctic. A scheme to build a pipeline from Inuvik in the North West Territory of Canada south-east towards Edmonton, Alberta, is less far advanced than the Trans-Alaska Pipeline System (TAPS) but in the circumstances may yet be the first to be constructed. The argument about the TAPS scheme has turned on two distinct issues—questions about the rights of native Alaskans to the ownership of land in Alaska and to royalties from exploitation of petroleum reserves and questions about the damage which might be done to the environment by a pipeline of the kind proposed. The difficulties over land ownership, complex though they are, seem well on the way to solution. The federal government still owns all but a small percentage of Alaska, but when Alaska was made a state of the Union in 1958, the new state was given the right to pick for itself close on a third of the 365 million acres not otherwise allocated. But for the past two years this right has been frozen pending a settlement between the federal government, the state of Alaska and the native population, reckoned to be about 100,000, about the amount of compensation to be paid for the extinction of traditional claims to land use or ownership. It now looks as if Congress is prepared to settle for $500 million in cash, at least that amount levied as a 2 per cent royalty on oil and gas leases and close on 7 million acres of land. Since this proposal, now being worked upon by the Senate Committee on Interior and Insular Affairs, goes some way to meet the claims of the native population, the chances are that procedural difficulties will not permanently interfere with the pipeline project. In the several public inquiries about the pipeline, native Alaskans and their representatives have indeed been conspicuous by their eagerness to see the project for a pipeline go-ahead. One of the ironies of the situation is that Mr Walter Hickel, the Secretary of the Interior, was Governor of Alaska and an enthusiastic developer until he joined the Nixon Administration two years ago.

The most serious obstacle to the building of the pipeline is the serious and persisting doubt about the effects of such a gigantic engineering project on the northern terrain. The pipeline is by most standards a gigantic undertaking. The pipe itself would be 800 miles long and 48 inches in diameter. The consortium of petroleum companies which constitute TAPS (Atlantic-Richfield, British Petroleum and Humble Oil) hopes that the ultimate capacity of the line will be two million barrels of oil a day, which works out at more than 100 million tons of oil a year. This is at once a measure of the productivity of the Alaskan oil fields and a sign of how anxious the petroleum companies are to open up the North American market—it has been estimated that the interest on the sums of money so far invested on the North Slope works out at more than $200,000 a day.

So why not dig a trench and bury the pipeline in it without more fuss ? The difficulty is that much of the route runs through or over the Arctic permafrost and that the petroleum companies are more or less bound to pump hot oil through the pipe. Indeed, the petroleum is likely to emerge from the wells on the North Slope at 80° C or thereabouts, and it has been assumed that this temperature would be maintained more or less the whole way along the pipe—heat lost to the surroundings would be made good at the pumping stations, of which there would be six to begin with and twelve when the pipeline was brought to full capacity. The most obvious problem is that such a pipe would necessarily thaw the permafrost through which it ran, with profound consequences for the terrain and potential danger for the pipeline itself, for subsidence and soil movement are among the most familiar results of thawing permafrost.

The difficulties of engineering construction in permafrost have been talked of at each of the public inquiries into the pipeline project, particularly that held in Alaska by the Department of the Interior and those held in Congress by the appropriate committees of the Senate and the House of Representatives. The general feeling seems to be that the hazards of building anything, a road, a railway or a house, in permafrost country are only now being catalogued. One of the difficulties is that the stability of the permanently frozen ground a foot or more beneath the surface may depend critically on the nature of the surface cover. Removing the covering of vegetation may be enough to set in train the progressive thawing of the underlying frozen layer. Making a road surface out of a compacted layer of gravel may either melt the underlying permafrost if the gravel is a less good insulator than the



Growth of the thawed cylinder around a pipe 4 feet in diameter with its axis 8 feet beneath the surface and its temperature at 80° C. Conditions on the left represent conditions near the Arctic coast and those on the right near the southern limit of the permafrost.

vegetation which it replaces or may increase the height of the permafrost table, if the insulating effect is greater than that of the original cover, thus setting in train processes of frost heaving. Problems like these plagued the Alaska Railroad ever since it was first begun in 1910 and it seems to have been only in the past decade that the Geological Survey intervened to show how one concrete and steel bridge was being moved as much as five inches each season simply because the concrete piers, on which the steel superstructure is erected, were thermally more conducting than the gravel which they replaced.

A particular hazard in permafrost construction is the occurrence of ice wedges at places at which surface water has been able to percolate down into the subsoil and freeze. Structures like these are responsible for the polygonal appearance of the terrain in permafrost country. If engineering structures are embedded in them, or placed on top of them, catastrophic melting may occur and one of the objects of the detailed survey of the pipeline route now being carried out in Alaska is intended to identify ice wedges of this kind. It seems now to be agreed that if the pipeline project goes ahead, the owners will be required to meet the full cost of clearing up after leakages of oil caused by cracking or distortion of the pipeline. The regulations devised by the Department of the Interior, which are acknowledged even by those who resist the pipeline to be more rigorous than others to which construction companies have been subjected, also require that the operators should make good any "land harmed or damaged" during the building or operation of the pipeline, but one of the bones of contention has been that nobody is really sure how to reduce permafrost to its original condition once it has been thawed.

The scale on which the permafrost would be disturbed by a buried pipeline has been spelled out in the past few days by some calculations carried out by Arthur H. Lachenbruch of the US Geological Survey and published as Geological Survey Circular 632. It is clear that the thermal effects of a buried pipeline would become apparent comparatively slowly in a period extending over two decades or more. It seems to be agreed that there need be no mechanical damage when the content of ice in the permafrost is comparatively small. The calculations suggest, however, that a 4 foot pipeline buried 6 feet in permafrost and operating at 80° C will thaw a cylindrical region some 20 or 30 feet in diameter within a few years and that, after 20 years or so, the permafrost will be thawed to a depth of 40 or 50 feet near the southern edge of the permafrost and between 35 and 40 feet in the north, where the permafrost is colder. One of the uncertainties of this kind of calculation, based on simple assumptions about the thermoconductivity of the materials involved, is that there is no way of knowing what will happen within a thawed out cylinder of ground. One possibility is that water would collect in such a channel, causing the material within it to flow as a kind of slurry and helping to extend the region within which the permafrost is no longer frozen.

The way in which such a structure might disturb the surface drainage pattern of Alaska is one of the sources of anxiety about it. There are horror stories from Alaska which suggest that badly sited tractor tracks can permanently affect the drainage of a large tract of land. The same phenomenon would have important consequences for living things, plants and animals. One of the hazards to be thought of is that the two Alaskan herds of caribou migrate across the proposed line of the pipeline, the most spectacular of them from the foothills of the Brooks Range in northern Alaska to the Northern Slope and back again. Nobody knows what effect a strip of soggy ground 30 feet or more in width would have on the migration of the caribou, but lesser changes in the environment, the building of new roads for example, have in the past markedly changed their ways.

The hazards of burying pipes in frozen ground and the danger that a buried pipeline carrying hot oil would affect life forms in the neighbourhood is one of the reasons why there is a tendency for the planners of TAPS to think of increasing stretches of the track above ground level. Originally, it was thought that only some 15 miles out of the 800 would be above ground, principally where the permafrost is laden with ice. According to Mr George Hughes, director of the TAPS project, it is now thought that 50 to 80 miles of the pipeline will have to be above ground. Some changes have been forced on TAPS by the need for river crossings at several places on the route from north to south, and ingenious schemes for suspending some sections of the pipeline as if they were suspension bridges are being discussed. Mr Hughes also said last week that studies are now being carried out at Houston on the assumption that the oil temperature will be more like 60° C than 80° C, but the study carried out by the Geological Survey would suggest that such a change of temperature would not markedly reduce the range at which permafrost would thaw but only the speed with which the new regime was established.

Experimental studies of pipelines like this are being carried out both for TAPS by the University of Alaska, which is running hot oil through a buried section of 48 inch pipe, and by a Canadian team concerned with the planning of the Mackenzie River pipeline. The possibility that a radically different design for the pipeline would help to reduce the risk of damage has not seriously been considered and indeed, so far as TAPS is concerned, it may be a little late to think of major modifications of the scheme now that much of the pipeline manufactured in Japan has already been delivered.

OCEANOGRAPHY

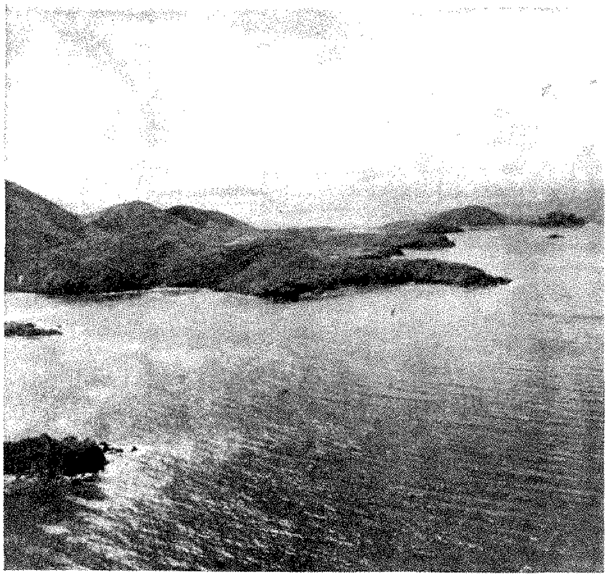
Living with Davy Jones

THE island of St John in the US Virgin Islands is now enlivened by the supporting services for an ambitious scheme for allowing fifty or more scientists of various kinds to spend intervals of two weeks or more on the sea bottom between now and the end of October. The scheme, known as Tektite 2, is based on a double-barrelled diving chamber built and operated by the General Electric Company, which has only this week staggered Wall Street with the news that it lost $42 million in the first quarter of 1970, chiefly because of strikes. This latest departure in underwater living follows a successful experiment a year ago at the same site in Great Lameshur Bay, on the south of St John. It differs from earlier sorties to the sea bottom such as the Sealab projects of the US Navy in being a means by which independent scientists can pursue diverse scientific objectives of their own. According to Dr Dail W. Brown of the Smithsonian Institution, which is spending between $50,000 and $75,000 of foundation money on the support of the scientific programme, applications from scientists to visit the sea bottom have been chosen on their scientific merits just as if the Tektite device were an oceanographic research vessel. The successful applicants for time come from universities, the independent oceanographic research institutes, government agencies such as the Geological Survey and even from private industry. But if the new submarine habitat is a unique vehicle for underwater research, it is also of practical interest to the US Navy, the National Aeronautics and Space Administration and the government of the Virgin Islands, all of which are among the sponsors of the enterprise. Also involved is the National Science Foundation, oddly enough as the sponsor of underwater spells by student technicians from three academic institutions, and the Department of the Interior, which has responsibility for mounting the enterprise as a whole and for spending something like $2 million on it.

For most of the time, the submarine laboratory, consisting of two cylinders 12 feet in diameter and 18 feet high connected by a tube 4½ feet in diameter, will be sited on a coral reef rising about 10 or 15 feet above the surrounding sea floor and at a depth of 50 feet. During the first six months, visitors will be able to spend up to eight hours a day in the water, and will be able to explore the neighbourhood of their vessels to greater depths. The crew of the vessel will consist of five people, one of them an engineer. There is also a smaller pressure vessel, with accommodation for two, which will operate towards the end of the programme at depths of up to 100 feet.

As the programme for Tektite 2 has developed, the most obvious common denominator is the opportunity provided by the new equipment for making more or less continuous observations of phenomena, physical and biological. To begin with, there will be measurements of fluctuations of pH, oxygen concentration and salinity, partly so as to provide some basic calibrations of usefulness of chemical samples taken from the reef. The first spell in the submarine vessels will also be a chance to test different kinds of fishing gear and bait with live fish. Early on in the series of dives, there will be attempts to make maps of the region and to follow the interaction between the sea and the sea bed. Throughout the summer, however, the local lobsters will be kept under careful watch, chiefly in the hope of making behavioural studies and of understanding the relationship between the animals involved in the underwater food chain. One of the questions of particular interest is the possible relationship between chemical variables, such as oxygen or carbon dioxide concentration, and the onset of migration among animals on the sea bottom and, as a part of that study, one of the visiting teams will establish an artificial community of animals on the sea bottom.

The particular interest of the Office of Naval Research and of NASA is in the biology of the people who will at various times visit the sea bottom and for this reason there will be daily samples of air and water from those who spend time in the diving bells. The interest of blood examination is considerable and there will also be an attempt to compile from the records of the visits to the sea bottom a more accurate series of decompression tables based on nitrogen and oxygen than exists at present.



The Tektite 2 site at Great Lameshur Bay, St John Island, US Virgin Islands.

British Visitors

MR ANTHONY WEDGWOOD BENN, Minister of Technology, and Sir Solly Zuckerman, the Prime Minister's Scientific Adviser, have been in Washington this week, Mr Benn at the invitation of Mr Maurice Stans, Secretary of Commerce, and Sir Solly Zuckerman for one of his periodic informal meetings with the Office of Science and Technology at the White House. Mr Benn has been at the beginning of a tour of the United States which will take him to the California Institute of Technology, Chicago and New York. One of the questions likely to have arisen in discussions with the National Aeronautics and Space Administration is the extent to which countries such as Britain may wish to collaborate in future programmes for space exploration. Sir Solly Zuckerman's interest seems to consist chiefly of environmental problems.

Investment in Freedom

from our Soviet Correspondent

AT a time when Soviet thought centres on the forthcoming Lenin Centenary, and the achievements of Soviet science and technology are being enumerated in honour of the leader, it comes as a jarring note that so eminent a physicist as Academician A. D. Sakharov, holder of the Order of Lenin and "father of the Russian atomic bomb", should cast doubts on the validity of the Soviet technological miracle.

This is not, of course, the first time that Sakharov has expressed doubts on this topic. In his open letter of 1968 he was already sounding a warning note. Side by side with his demands for greater intellectual freedom, the abolition of censorship and the like, he drew to the attention of the planners the danger inherent in pollution both from industrial wastes and from the over-lavish use of chemicals in agriculture, and the ruining of the natural resources of the Union by "senseless despoliation caused by local, temporary, bureaucratic and egotistical interests, and sometimes simply by questions of bureaucratic prestige. . . ." Yet at the same time, he could offer a qualified comfort from the fact that, in industrial fields, the Soviet Union did seem to be slowly overtaking its rival. One should not, however (so he implied), rely on absolute figures alone, nor draw too great a comfort from the raw data. The Soviet Union was catching up with its rival chiefly in those "old traditional industries" (coal and steel, for example) which were no longer so vital a part of the US economy, whereas in newer fields such as automation, computers, petrochemicals and industrial research and development in general, Soviet progress was not only lagging but had a slower rate of growth, "so that a complete victory of our economy in the next few decades is unlikely".

One must also remember, he warned, the "ski-track" effect. When one skier starts ahead of the other, it is difficult to assess their relative strength. "The skier in the striped jacket broke the snow, while the one in the red jacket did not have to."

But in spite of these important qualifications, in 1968 he concluded that "we have demonstrated the vitality of the socialist course which has done a great deal for the people materially, culturally and socially".

And now, twenty-one months later, another such open letter is circulating from hand to hand through the academic circles of Moscow. Here the keynote is one of increasing gloom. The Soviet Union surpasses the United States in the mining of coal, true, but lags behind in oil drilling, far behind in gas drilling and in the production of electric power, hopelessly behind in industrial chemistry and is virtually a non-starter in the computer field. "One can only say that we are living in a different epoch."

If the Soviet Union is not to degenerate into a second-rate provincial power, considerable rethinking of industrial planning to meet the new age is essential. Expanding this point, Sakharov points out the very real wastage to Soviet science imposed by censorship laws. "Exchange of information with foreign countries is hampered for fear of the penetration of hostile ideology." Within the Union itself, "information on our shortcomings and unfavourable phenomena is kept secret, lest it be used for propaganda against us", while new and bold theoretical concepts and practical proposals are quashed without discussion, in case they might prove too disruptive. "The desire of the intelligentsia for greater freedom is legal and natural"—and, he implies, is also a powerful tool in economic and technological progress. The "restrictions, administrative pressure, dismissals and, even, the conducting of trials" imposed by the bureaucrats produces, therefore, an ever-widening gap between intellectuals and state-planners, a gap which, in present conditions, "must be termed suicidal".

The wastage of manpower, or rather of brain-power, due to the imprisonment, or internment in mental homes, of intellectuals, for opposition "in the field of ideas and convictions" is equally deplored. A further wastage seems inherent in the current policy towards the non-Russian nationalities within the Soviet Union. The nationality question is a large problem linked with the whole system of internal passports, without which movement from place to place is impossible, and the evidence of recent literature at least (notably the novel *The Cathedral*, by the Ukrainian novelist Oles' Honchar) suggests that the passport scheme is being used as a means of keeping promising young people "down on the farm" irrespective of whether they might perform a more productive and beneficial function elsewhere. At all events, the eventual abolition of the internal passport system is one of the fourteen points in the plan for the salvation through "democratization" which Sakharov proposes for Soviet industry and technology.

On the whole, the other points proposed are Fabian rather than spectacular in tendency. Against the suppression of distasteful, but necessary, information on the true state of the country, he counsels a "restricted distribution (via party and state organs)" of such information to those most in need of knowing. It is only later that this type of material should gradually be made accessible to everyone. The problems of "democratization" (free interchange of information, and the use even of critical minds in the planning of industry) should be, he advises, discussed through the Soviet press. The party should commit itself to the concept of democratization, which will "restore to our ideological life its dynamics and creative nature", and abolish the current "bureaucratic, dogmatic and hypocritical" attitude of officialdom.

Finally, it should be observed that Sakharov's approach seems largely pragmatic. While it is "legal and natural" to desire greater intellectual freedom, the granting of such is urged not on ethical grounds but as a practical means of providing a forward-looking and progressive technological advance into the seventies. Antidemocratic traditions, he says, are a relic of Stalinism. No longer (in another of his home-spun parables) can the lorry of progress be driven with one foot on the accelerator and the other on the brake. Current policies will lead to a technological and economic standstill. Democratization is the only sound policy. "At the present time, we still have a chance to take the right road and carry out the reforms we need. In a few years, perhaps, it may be too late !"

How to Sell the Social Sciences?

by our Special Correspondent

Paris, Wednesday

THE times are propitious for the social sciences to win funds and influence government policy. But how can the customers' good will best be exploited when on past performance the social sciences (economics excepted) have relatively little to offer to the decision making processes of government? The problem of dressing a nearly empty window was, in rather more words, the chief preoccupation of the conference held at the Unesco building in Paris this week on social science policy.

The occasion was made more than purely academic by the presence of several delegates responsible for formulating their country's research policy. Indeed, Mr Andrew Shonfield, chairman of the British Social Science Research Council, was positively optimistic about the part the social sciences have to play in government at some time in the future. Compared with economics, their present influence is on the whole trivial but then the economic indicators which have proved invaluable simply for measuring trends were only developed within the past 40 years. There is no reason why similar indicators should not also be developed in the social sciences, although, of course, the attainment of respectability is not furthered if on the rare occasions when a sociologist's views are adopted as a guide to policy his colleagues "tend to see it in terms of a sleight of hand by which one of their number has managed arbitrarily to capture and use the power of a politician, in the sort of way that Lysenko used Stalin".

An outstanding example of the philosopher becoming king is, of course, the way in which the report on negro family structure made by Mr Daniel Moynihan in 1965, when he was assistant secretary of labour, was adopted by President Johnson as the basis for a whole programme of reform. If the social sciences have so few successes of this nature to their credit, that could be because of the crudity of their theoretical apparatus when compared with the comprehensive embrace of economics. An economist who makes a recommendation on money supply, Mr Shonfield pointed out, is not surprised to be asked how this may affect the level of employment in the building industry in Northern Scotland; but the sociologist advising on a change in structure of primary schools would be unable to say how this might impinge on the operations of authority in the factories.

A different reason for the "lack of popularity of the social sciences among the decision-makers" was suggested by Dr Hemming Friif, director of the Danish National Institute of Social Research; "either the scientists are criticizing the government or they deal with matters which are looked on as esoteric to those grappling with the pressing problems facing their country". Ivory towers also loom tall in the demonology of Professor D. Goldschmidt, director of the Max-Planck Institute for Educational Research, who accused university sociologists, in Germany at least, of being more interested in establishing their subject as an academic discipline than in translating it into practice, as the student movement are rightly demanding that they should do.

If not in the method, are the reasons for this modest achievement to be sought in the men or the means? The human material was blamed in a discussion between the scientific secretary and the chairman of the Social Science Research Council at the second morning session. Mr J. Mitchell frankly confessed that although the SSRC receives only 2·6 per cent of the total budget for the five scientific research councils in Britain "we none the less have great difficulty in spending this money usefully". No less than 65 per cent of the grant applications made to the SSRC are rejected because of poor quality. Money therefore is not a restraint, but although the SSRC has spent half its budget since 1965 on postgraduate training in the hope of improving supply, Mr Mitchell avowed himself "very gloomy that we will get a substantial supply of competent research workers". His pessimism sprang in part from the belief that there is in the social sciences the lack of a clearly defined research tradition such as distinguishes the natural sciences, nor any consensus as to what is good research and what is bad research.

In response to this public washing, the work of the PEP and the Native School of Anthropology was held up as examples of British linen not being as dirty as was alleged. But Mr Shonfield agreed with his colleagues' diagnosis, at least as a general point that probably affected other countries as well. There has been quite a lot of top talent in the social sciences in Britain, he said. But the vast expansion of recent years had rushed people into professorial chairs at a premature stage in their careers. This dilution of talent was the cost of expansion.

These self-criticisms seemed to appertain to a different world to that described by Dr Henry Riecken, president of the Social Sciences Research Council in Washington, who mentioned that there are about 110,000 social scientists active in the United States enjoying some 800 million dollars of support from federal funds, foundations and other sources.

What use have the social scientists made of this kind of money? Professor A. B. Cherns of Loughborough University, the organizer of the conference, pointed out that federal expenditure on research in the social sciences amounted to an estimated $333 million in 1968, but that, in response to congressional enquiry, agencies were unable to describe the use made of previous research. But stewardship in the social sciences, Professor Cherns argued, is not just a matter of talent. "Research can only have a specific use if it is conceived as taking a narrow view of the problems it is tackling."

On the showing of the conference it may be hard to define what assistance the policy-maker can legitimately expect from the social sciences, or on what lines social science policy should be planned. But then, as Professor B. Suchodolski of Warsaw remarked, "We have never had any example of state government by sociologists and it might be doubted if such a vista for the future would be a tempting one".

NEWS AND VIEWS

Basic Questions about Moon still in Doubt

Nobody really expected the lunar samples to solve all the problems of the solar system in one swoop, yet it is surprising how little basic understanding of the Moon has been revealed since Apollo 11 nine months ago. This was clear at the NATO Advanced Study Institute on the Moon and Planets which began at the University of Newcastle upon Tyne last week.

It is true that a vast amount of raw information is available in the form of 120 pounds of rock and soil returned so far. There is also the information produced by the instruments left behind on the surface of the Moon, although nobody knows quite what to make of the seismometer results. And on top of the information obtained at first hand there are the data from a decade of unmanned probes to the Moon, culminating in the Surveyor and Orbiter series in the late 1960s.

But basic problems such as the nature of the interior of the Moon and the forces which moulded the lunar surface are still open to vigorous discussion, as the Newcastle conference is demonstrating. And, as well as the failure to answer the questions about the Moon and the solar system in general which have always been a puzzle, the space programme has set further problems which the samples have so far failed to answer. Nobody would have it otherwise, of course.

The concentrations of mass under some of the ringed maria, which close analysis of the paths of spacecraft in orbit around the Moon has revealed, are one example. Another is the nature of the soil which blankets the parts of the Moon visited so far to a depth of metres. It seems clear from the composition of the soil that it could not have been created by the grinding up of the igneous rocks which have been found on the Moon, including the anorthosite which is suspected to be the chief component of the highlands. The age measurements—$4\cdot65\times10^9$ years for the soil compared with a range of $3\cdot59$ to $3\cdot93\times10^9$ years for the rock samples—also argue for the uniqueness of the soil and are a further obstacle to a simple explanation.

Naturally enough, the discussion centres on the nature of the interior of the Moon, and here the mass concentrations are taken to be the primary clue, although the weak magnetization of the samples is an important indicator seeming to imply that the Moon once had a conducting liquid core.

Much depends on the extent to which the gravity maps produced from the Orbiter data are to be trusted, but it seems that the contours are more like what would be expected if the mass is concentrated in plates under the maria than the prediction for spherical bodies buried under the surface such as slow-moving meteorites might conceivably produce. This is a question which requires the tracking of spacecraft in low altitude orbits which are more susceptible to gravitational inhomogeneities than the 100 km orbits of the Lunar Orbiter series. This is something for later Apollo missions. If the mass is indeed concentrated into plate-shaped structures, then this is a strong argument in favour of the view that the gravity effects can somehow be explained in terms of the evolution of pools of lava. Yet some people believe there is a problem in accounting for the way in which the mass is supported, and suggest that this implies a cold lunar interior. The evidence for molten material at the surface must then be explained by a process such as heating by the Sun during an early superluminous phase.

The question which is beginning to surface in people's minds is whether the exploration programme which has been laid out to 1974 is going to supply the information to solve the problems which are still outstanding. It may be that material from the diverse sites which have been earmarked for exploration will throw a new light on the data which have so far been accumulated purely from landings in the maria. There is the possibility of picking up material from deep within the Moon which has been thrown out by meteorite impact, for example. This must be what people are hoping, if the fundamental questions about the nature of the Moon are to be answered.

Mapping the RNA Phage

Molecular biologists, always in pursuit of new clues to the mechanisms of protein synthesis, are at present very excited about RNA bacteriophages. This enthusiasm springs from the remarkable ease with which the *in vivo* situation can be mimicked in the test tube when these viruses are used. A flood of recent articles has been concerned with the nucleotide sequences of the genes themselves, the structure and function of the punctuation signals between the genes and the ways in which the translation of one gene may control the translation of others by causing changes in the secondary and tertiary structure of the RNA. On page 230 of this issue of *Nature*, Jeppesen, Steitz, Gesteland and Spahr report the first unambiguous determination of the order of the genes of phage R17.

RNA phages code for three proteins, phage coat protein, maturation (A) protein and RNA synthetase enzyme. Because there is no genetic recombination between RNA phages, it is not possible to map their gene order by conventional genetic analysis. Attempts have been made, therefore, to achieve mapping by following the way in which they direct the syntheses of their three protein products. This approach has depended on the assumption that their translation is similar to that of messenger RNA of bacterial operons, and in hindsight it is now clear that this assumption is unjustified and has led ineluctably to the conclusion of incorrect gene order.

When a bacterium is infected by phage, different amounts of the three phage proteins are produced, roughly in the proportions 20 : 5 : 1 coat : synthetase : maturation. This led to the suggestion that the order of genes from the 5′ to the 3′ end of the molecule in the phage was coat–synthetase–maturation, ribosomes attaching only at the 5′ end and sequentially translating the messenger, but with some ribosomes dissociating from the messenger at the end of each gene so that decreasing amounts of each protein are produced. This is consistent with the finding that the translation of the coat protein gene is necessary before it is possible to translate the synthetase gene. This theory had to be modified when it was found that, although synthetase protein is not produced until some time after infection, both coat protein and maturation proteins are produced almost immediately (albeit in different quantities). Thus it was suggested that ribosomes can attach to both the coat gene and the maturation gene (although with a lower affinity in the latter case), but cannot do so to the synthetase gene; this is translated only by ribosomes which have passed into it after translating the coat gene.

Unfortunately for this model, recent work has shown that each of the three phage genes commences with an initiation sequence of nucleotides which can bind ribosomes directly. If a complex of ribosomes–phage RNA is digested with nucleases, these initiation regions are shielded against the enzymatic degradation and remain intact. They can then be isolated and characterized by the oligonucleotide digestion fingerprints produced by treatment with T1 ribonuclease. Each of these three initiation regions has been identified in this way (*Nature*, **224**, 957; 1969).

Jeppesen *et al.* have made use of this finding to produce a genetic map of phage R17 by biochemical analysis. The enzyme ribonuclease IV from *E. coli* cleaves the phage RNA at a position about 40 per cent along the molecule from the 5′ end. The initiation regions present on each of the fragments were identified by degrading the fragment–ribosome complexes with nucleases and characterizing the protected regions of each. The maturation protein gene initiation sequence is present in the 40 per cent fragment only; the coat protein gene initiation region also appears primarily in this fragment, and the synthetase gene initiation region is present primarily in the 60 per cent fragment.

These data make possible unambiguous determination of the biochemical map of the phage. The coat protein gene must lie in the middle of the messenger because the oligonucleotide T1 fingerprints which correspond to the 5′ end of its initiation region appear in the 40 per cent fragment, whereas nucleotide fingerprints corresponding to internal parts of this gene appear in the 60 per cent fragment. The precise site of attack of ribonuclease IV seems to lie in the nucleotide sequence which codes for the first six amino-acids of the coat protein. The highly localized yields of the initiator sequences of the other two genes show that the maturation must lie in the 40 per cent fragment and the RNA synthetase in the 60 per cent fragment. In agreement with this conclusion is the previous finding (*Proc. US Nat. Acad. Sci.*, **59**, 879; 1968) that when the two fragments are used to direct protein synthesis *in vitro*, the 40 per cent is relatively inactive as messenger, but the 60 per cent efficiently directs the synthesis of synthetase protein. Coat protein is not produced efficiently by either fragment. Thus the order of genes in the phage must be: 5′-maturation–coat–synthetase-3′.

This comprises the final nail in the coffin of the coat–synthetase–maturation gene order model. How then is the differential expression of the three phage genes to be accounted for? It seems that ribosomes can bind directly to the initiation regions of each gene; perhaps this binding may be of differing efficiency in each case. This is supported by the different yields which are obtained of the three initiation regions. The affinity of the regions for ribosomes is probably influenced not only by their particular nucleotide sequences, but also by the secondary and tertiary structure of the phage RNA. That the coat protein gene must be translated before the synthetase gene can be translated can now be interpreted to imply that changes in the secondary and tertiary structures may be brought about by the binding of ribosomes to the coat gene initiation region; these changes could control the extent of availability of the synthetase initiation region.

MICROSCOPY

Thinking Small

from our Molecular Biology Correspondent

EVEN those physical chemists or biochemists to whom the very idea of trying to see a molecule, or even its incinerated shell, savours of cheating have had to recognize that the electron microscope is here to stay. That the modern instrument is fast approaching the theoretical limits of resolution has been some reassurance, but recently a sinister new threat to their livelihood has been taking shape. This is the scanning microscope which Crewe in Chicago had been developing. An account of the principles of the design in comprehensible form for the general reader, and some examples of what the machine can do, are now available for public contemplation (Crewe and Wall, *J. Mol. Biol.*, **48**, 375; 1970).

In the scanning microscope, as commercially available, the specimen is traversed by a focused electron beam, and it is the secondary electrons emitted by the sample that are detected. It is a blunt instrument, however, limited by the emissivity of the tungsten filament source, which produces a spot of not less than about 100 Å. Crewe and Wall nevertheless opted for the scanning principle as a basis for a high-resolution instrument, partly because the focusing system makes it possible to operate on a very small field, and also because of the important feature that the contrast need not be linked to resolution. They work, however, with the electrons transmitted by the sample, rather than the secondary emission. A central technical problem was to devise a source capable of producing very high intensity in a small spot. The electron gun design was based on the metal tip field emission source, which gives about a million times the brightness of a conventional hot filament, and can be focused to give a spot of about 5 Å. Many other formidable technical problems and their conquest are described by Crewe and Wall, though from their description it seems that at least in a manipulative sense their instrument is simpler to align and use than a conventional electron microscope.

The results show great promise. A picture of a T4 bacteriophage shows a high degree of detail in the tail sheath; in rods of tobacco mosaic virus, stacked protein disks are resolved with great clarity; and in single molecules of the protein ferritin, the subunits and the ferric cores can be clearly discerned.

A further facility that the instrument offers is measurement of the energies of the transmitted electrons. The energy loss on passing through a specimen is a function of the material, and the measurement of energy loss distribution should thus open up analytical applications, as well as the possibility of increasing the contrast by choosing the most favourable energy band for detection.

Electron microscopists will no doubt be waiting anxiously to see whether the promise of high contrast at the best resolution is fulfilled; in a new review also just published (*Quart. Rev. Biophys.*, **3**, 137; 1970), Crewe has already reported the probable detection of single chemical substituents, containing clusters of heavy atoms, in DNA, so that the strategy evolved by Beer and his colleagues of sequencing nucleic acids with the electron microscope may soon be realized.

ENDOCRINOLOGY

Hormones in Cells

from a Correspondent

An eminent collection of people with an interest in hormones met in Bristol from April 5 to 11 to discuss subcellular organization and function in endocrine tissues. Professor Marilyn Farquhar (University of California School of Medicine, San Francisco) described how in the adenohypophysis excess hormone-containing granules are incorporated into lysosomes. Future research may well centre around control systems determining intracellular recirculation of granules to the Golgi apparatus and the direction of granule transport in cells.

Professor I. Geschwind (University of California, Davis) indicated that a possible site of action of calcium during its mediation of the secretory process was on the intracellular microtubular system evolved to direct granules to specific sites on plasma membranes for secretion. Later, Dr E. K. Matthews (University of Cambridge) suggested that calcium induced secretion by reducing the intracellular viscosity and the energy barrier arising from the surface charge on the granule and the inner face of the plasma membrane, thereby permitting fusion of the granule and cell membranes.

Professor W. W. Douglas (Yale University Medical School, New Haven) provoked much discussion with morphological evidence which apparently indicated that the neurohypophyseal hormones are secreted by exocytosis. This would involve the inward budding of the plasma membrane, subsequently transported centripetally as microvesicles. There were doubts as to whether this rarely observed process of a two-way axonal or cellular transport system of hormone storage and microvesicles could be the physiologically significant route for granule secretion. The alternative between the existence of an "extragranular hormone pool" and exocytosis as mechanisms for hormone release was discussed by Dr R. P. Gould (Middlesex Hospital Medical School, London), who suggested that the site of fusion of the granule and cell membrane could become an area of increased permeability permitting the outward movement of high molecular substances.

Drs F. S. LaBella, S. Shin and S. R. Vivian (University of Manitoba, Winnipeg) reported the existence of six neurophysins, but the consensus of opinion on present evidence settled the number at three. During a session on neuroendocrine organization detailed comparisons were made between neurosecretory systems in invertebrates and vertebrates. It seems that comparative research determining possible carrier proteins for neurohypophyseal hormones in vertebrates may prove rewarding and of significance in understanding the vertebrate system.

Professor Dorothy Hodgkin (University of Oxford) described the most recent model of the structure of insulin. She also commented on correlations between species amino-acid differences in the insulin molecule which are located on the "exposed" surface of the molecule with differences in the hexagonal laminated structure of the insulin granule. She agreed with Professor H. Heller (University of Bristol) that the molecular configuration of protein and peptide hormones and their carriers may well have a direct effect on the morphology of the hormone granules, thus providing a "bridge" between molecular and ultrastructure.

In a session devoted to catecholamines Dr J. Häggendal (University of Göteborg, Sweden) presented some new information about the uptake of exogenous noradrenaline chiefly by newly formed amine storage granules. Dr A. Pletscher (Hoffmann-LaRoche Co., Basle) had evidence for the storage of biogenic amines *in vivo* as high molecular weight aggregates of ATP, produced by stacking together molecules of the nucleotide. Professor J. P. Green (Mount Sinai School of Medicine, New York) considered the reactive sites on the histamine (the amino-acid group of the side chain and pyridine-like ring nitrogen) and 5-hydroxytryptamine (primary amino group of the side chain and specific electrons of the indole ring) which would form linkages for binding in granules.

NUCLEIC ACIDS

Precursors and Products

from our Cell Biology Correspondent

Messenger RNA molecules undoubtedly exist in the cytoplasm of eukaryotic cells, but precisely how they get there is something of a mystery. In the early nineteen sixties it was tempting to assume that the heterogeneous and high molecular weight RNA which occurred in nuclei and was rapidly labelled with short pulses of labelled bases was mRNA. After all, heterogeneity of size and rapid turnover are characteristics expected of a pool of mRNAs. But between 1963 and 1966 it was proved to everyone's surprise that most of this rapidly labelled nuclear RNA never leaves the nucleus let alone functions as messenger programming cytoplasmic polysomes.

The picture has changed little since then and the latest attempt to prove a relationship between heterogeneous nuclear RNA and mRNA (Soreiro and Darnell, *J. Cell Biol.*, **44**, 467, 476; 1970) is, like its predecessors, ambiguous. To decipher the events between synthesis of mRNA and its functioning in the cytoplasm it is necessary to follow the fate of a specific mRNA, and so far this has proved impossible. At present the best that can be done is to seek common base sequences in mRNA fractions and any putative nuclear precursor, such as heterogeneous nuclear RNA, by competitive hybridization experiments. The great snag to this approach is that molecules with related but not identical sequences competitively hybridize with DNA as if they had identical sequences. Even after taking all precautions to maximize the resolution of this technique, as Soreiro and Darnell have done, the most that can be said is that mRNA and heterogeneous RNA have similar base sequences. Similar amounts of the two RNAs from HeLa cells bind to a given amount of DNA and presaturation of the target DNA with cold heterogeneous RNA reduces the amount of hot mRNA or heterogeneous RNA that can hybridize. A small fraction of the heterogeneous RNA may therefore be a precursor of mRNA if the heterogeneous RNA molecules are cleaved before migrating to the cytoplasm to act as messenger.

The intranuclear maturation of ribosomal RNA is the obvious precedent for a maturation process involving specific cleavage. According to Weinberg and Penman (*J. Mol. Biol.*, **47**, 169; 1970), in HeLa cells infected with polio virus (when infection induces the accumulation of ribosomal precursor RNAs) the chief route of maturation includes four steps. A 45S precursor containing the sequences of both 18S and 28S ribosomal RNA is synthesized only to be cleaved to yield a 41S molecule and a small fragment which is degraded. The 41S molecule is cleaved again into a 20S and 32S molecule; these finally give rise to 18S and 28S ribosomal RNAs when short fragments are clipped off. The whole process boils down to elimination by specific cleavages of nearly half the original 45S precursor.

The next step in ribosome assembly, the association of ribosomal proteins to ribosomal RNA, also proceeds in a stepwise fashion, giving rise to discrete subribosomal particles. In *E. coli* the ribosomal proteins fall into at least three groups, each associating at a characteristic rate. Various values for the half-lives and pool sizes of individual ribosomal proteins have been reported and there is a modicum of agreement with the differences perhaps attributable to differences in culture conditions and strains used. Sells and Davis (*J. Mol. Biol.*, **47**, 155; 1970), for example, recently reported half-lives of individual ribosomal proteins ranging from 2 to 11 min with pool sizes varying from 1·7 to 9·4 per cent of the total ribosomal protein pool.

A particle sedimenting at 43S seems to be the immediate precursor of the 50S ribosomal subunit. Forget and Varrichio (*J. Mol. Biol.*, **48**, 409; 1970) believe that in *E. coli* K12 growing at its maximum rate the availability of protein rather than some metabolism of the ribosomal RNA limits the rate at which 43S particles become 50S subunits. They found that the 43S particle has the same 5S/23S RNA content as the mature subunits although the 5S RNA is less firmly bound to the precursor. Moreover, they could not detect any differences in the chemistry of the RNAs from precursor particles and mature subunits. At least in conditions of maximum growth the supply of proteins therefore seems to be the bottleneck.

PHYTOCHEMISTRY

Terpenoids for Progress

from a Correspondent

KNOWLEDGE of the terpenoids is growing fast, as members of the Phytochemical Society showed when they met in Liverpool on April 7 to 10 to discuss the biochemistry of these compounds. Many speakers pinpointed an important recent development when they demonstrated convincingly that polyisoprenoids in their many forms can no longer be ignored as "end products" or backwaters of secondary metabolism. The importance of the terpenoids in ecological interactions was highlighted by Professor R. B. Clayton (Stanford University), who said that such informationally rich compounds may well have contributed to evolution from prebiotic times. Another notable theme of the meeting was the analogy between reactions in terpenoid biosynthesis and well known transformations in organic chemistry, for example, in the cyclization of squalene 2,3-epoxide to lanosterol.

Dr A. Pfiffner (Hoffmann-LaRoche Co., Basle) described a series of syntheses of the eight geometrical isomers (all racemates) of the juvenile hormone of insects. Biological assays carried out with each isomer showed that usually the natural isomer was the most active, but there were species differences. The 2-*trans*,6-*cis*,10-*cis* isomer turned out to be more effective in causing sterility in some insects.

Dr M. J. O. Francis (University of Oxford) suggested that monoterpene glycosides, which are equally soluble in organic solvents and water, would provide a plant with an ideal mechanism for glucose transport. This would be analogous to the function of polyprenol phosphate in bacterial cell wall synthesis.

Dr J. Macmillan (University of Bristol) underlined the importance of the work of West *et al.* in solving major enzymological problems in gibberellin biosynthesis, with the result that, although much remains to be done, the overall pathway (at least in fungi) seems fairly clear. One reaction he mentioned which has no counterpart in organic chemistry is the hydroxylation of a tertiary (bridgehead) carbon atom.

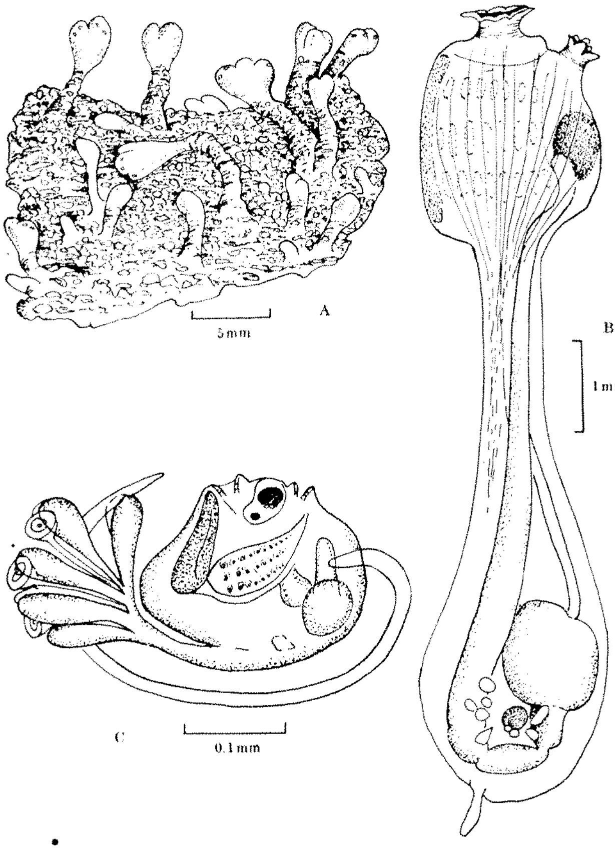
Professor T. W. Goodwin discussed the thesis that only by comparing carotenoids produced at the end of the proposed biosynthetic pathways (rather than the intermediates) could significant conclusions be drawn when interrelating the species that contain them (in this case the algae). Dr S. L. Jensen (Institute of Technology, Trondheim) insisted that many recently discovered carotenoid structures which have been in part deduced from mass spectral data must be confirmed by synthesis. Several speakers also made it clear that pathways deduced from the patterns of naturally occurring compounds of related structure can only be regarded as tentative when evidence is lacking at the enzyme level.

The notable recent increase in new structures was illustrated by Professor V. Herout (Academy of Sciences, Prague), who dealt with the sesquiterpenes: more than 100 types of carbon skeleton are known in this group, which must present a rich supply of experiments for biosynthetic work.

MARINE BIOLOGY

Underwater Guide

An eagle eyed underwater zoologist who recognizes these creatures attached to a nearby rock should know that he is in the vicinity of Plymouth or North Carolina, or perhaps off the coast of France. This detail of geographical distribution he would have learnt from R. H. Millar's new handbook, *British Ascidians*, the latest of the Linnean Society's synopses of the British fauna (Academic Press, £1 2*s*). The book contains keys to the families and species of ascidians to be found in British waters, as well as notes about individual species. This illustration, one of many, shows (*A*) part of a colony, (*B*) a zooid and (*C*) a larva of *Archidistoma aggregatum*. (Several zooids are housed within each projection on the colony.)



THERMODYNAMICS

Keeping Up to Date

from a Correspondent

Thermodynamics still holds surprises, as delegates learnt at the international conference on this topic held at Cardiff on April 1–4, under the auspices of the Institute of Physics and the Physical Society. The organizers judged correctly that the survival value of the subject lies first in its breadth (delegates included chemists, engineers, mathematicians and physicists) and second in its adaptability. Thermodynamicists are willing to dilute the classical purity of their doctrines and open judicious doors to new recruits. For example, it is possible that they are making a take-over bid for parts of cosmology. Dr D. Layzer (Harvard) presented a fascinating account of how the cosmological "arrow of time" could be linked with thermodynamic irreversibility by arguing that initial conditions in a Friedman universe were probably such as to generate high initial information and low entropy. The subsequent increase in entropy is then linked to the growing information embodied in history. Layzer's viewpoint is epitomized in his remark: "Structure and order are tricky. We should keep to well-defined concepts like information."

Well within the classical tradition was a new sharpening of Gibbsian thermodynamics which dealt in some detail with phase changes and solution processes occurring in elastically stressed systems. This extension, by Dr A. G. McLellan (Christchurch), has been made by defining suitable extensive coordinates which describe the shape of a crystal. Successful applications have been made to the α–β quartz transition, crystal twinning and homogeneous diffusion. The work is likely to have important applications in geophysics.

The other classical topic discussed at some length was the question of axiomatics. Dr R. Giles (Kingston), who several years ago provided the first really fresh approach to thermodynamics since the time of Carathéodory, was urging a pedagogical version of his system on a somewhat unwilling audience, most of whom sympathized with the remark of Dr M. W. Zemansky (New York): "Work is anathema. In Britain, I sometimes think that heat is anathema. But work and heat are here to stay." Dr W. J. Hornix (Nijmegen) reported progress with the (axiomatically) least satisfactory aspect of thermodynamics—the treatment of chemical systems of varying composition.

Much was said about irreversible thermodynamics which has been part of the extended domain for at least twenty years. The two chief branches of this subject are the mathematical neo-Cauchy theories expounded, for example, by Truesdell, and the physico-chemical theories of relaxation and transport started by Onsager. No significant new contribution was offered at Cardiff, but it seems clear that both subjects are still moving, presumably because people have faith that their unfulfilled promise will be redeemed.

There were interesting accounts of dynamical calculations on finite models which illuminate the passage to equilibrium in isolated systems. Typical of these was work by Dr J. Ford (Atlanta) in which two or three oscillators were coupled by non-linear resonant interactions. The Arnold stability of orbits can be dramatically broken in a way which renders the motion substantially ergodic. This has been shown by machine computation of the orbits. At the other extreme Dr S. Fujita (Buffalo) announced a new formulation of the many-body problem in which the infinite hierarchy of coupled equations is replaced by a single closed equation for the one-particle distribution function. As he remarked: "There are many, many methods, and you can use any one of them to derive desirable results."

There were some sad absentees: nobody said anything substantial about biological thermodynamics, nor about critical phenomena, which received a brief but illuminating mention in a survey by Dr L. Tisza (Cambridge, Massachusetts). But the full proceedings, which are expected to be published in July, should include an important paper on the analytical description of critical points by Dr M. H. Coopersmith (Virginia), who was not able to read his paper at Cardiff.

JOSEPHSON EFFECT

Making Way for a New Volt

by our Solid State Physics Correspondent

THE Weston cell may be on its last legs as an international standard of voltage because of the rapid progress in developing high precision measurements of the a.c. Josephson effect. T. F. Finnegan, A. Denenstein and D. N. Langenberg (*Phys. Rev. Lett.*, **24**, 738; 1970) have wrought several changes in the apparatus which provided W. H. Parker *et al.* (*Phys. Rev.*, **177**, 639; 1969) with a value for the ratio *e*/*h* to a precision of 2·5 parts in a million, and have improved on the accuracy by a factor of five. This puts the measurements within touching distance of the accuracy claimed for voltage determinations from Weston cells and makes it virtually certain that the cell will soon be ousted as a voltage standard in favour of the far more elegant solid state device.

The real attraction of the a.c. Josephson effect, in which the voltage across a junction varies with the frequency of the supercurrent, is its independence of the shape of the junction. Different sets of apparatus will give the same characteristics, as Parker *et al.* found in their determinations of the ratio *e*/*h*, which relates the frequency to the voltage. Frequencies, moreover, are very easy to measure accurately, being independent of temperature and extraneous effects. What Finnegan *et al.* have achieved is to increase the precision of the experiment to the point at which the ratio can be redefined as an auxiliary constant, allowing a voltage standard to be established in terms of frequency.

Comparison of the junction voltage with a reference cell provides the limiting accuracy in *e*/*h*. In previous determinations a conventional potentiometer was used with adjustable resistances, but Finnegan *et al.* have capitalized on the potential of a Josephson junction as a variable voltage source by allowing microwave radiation of a chosen frequency to interact with the supercurrent to give the desired voltage. A fixed ratio resistance network can then be used. They have also managed to raise the Josephson voltage by a factor of ten, to 10 mV, which reduces noise factors and lead resistance corrections and improves the voltage ratio with the standard cell. With further modifications, they are confident that *e*/*h* will soon be known to less than 0·1 p.p.m. and see attention shifting to the problem of how to disseminate the standard volt, once established in a Josephson device, to different parts of the globe.

The results of Finnegan *et al.* are likely to be discussed at the forthcoming conference at Gaithersburg, near Washington. Similar experiments at the National Physical Laboratory are expected to be ready in time for the conference on atomic masses and related constants at the NPL in September 1971, but it seems that the fate of the volt will have to await the next international meeting on standards due to be held at Sèvres, near Paris, some time within the next five years. Certainly the present system in which the ampere, measured by the force between two wires, is taken as the primary electrical unit will come under fire. The ampere can only be reproduced to an accuracy of about 4 parts in a million.

The fine structure constant α is related to *e*/*h* by the gyromagnetic ratio of the proton. Finnegan *et al.* point out that if α could be measured to better than one part in a million, their new value for *e*/*h* would provide a superior determination of the gyromagnetic ratio than that available from direct experiments.

PHOTOGRAPHY

Shock Tactics

from a Correspondent

A COMMON interest in shock wave phenomena brought together the Association for High Speed Photography and the Shock Tube Liaison Group at Liverpool between April 6 and 8. Early in the meeting a cautionary note was struck by Professor P. L. Clemens (von Karman Institute for Fluid Dynamics, Brussels) when he discussed the analysis of schlieren photographs. The marked lack of correlation in data obtained from these photographs of the flow about very high speed bodies, particularly in the wake region, indicated a requirement for a general sensitivity definition, he said. Clemens formulated such a definition, taking account of the human element in the form of the sensory nature of vision, and including the behaviour of the photographic materials and the optical arrangement of the schlieren system.

Holography attracted considerable interest, and applications to the study of shock phenomena and to the investigation of small particles moving at very high speed were described. Dr J. C. W. Gates (National Physical Laboratory) discussed the use of pulsed lasers and holographic recording in shock tubes and wind tunnels. The potential advantages included the study of variations in three dimensions from a single record, and also making several more or less independent measurements from one record by multiple reconstruction. From the economic point of view it may not be necessary to buy expensive optical equipment for this type of work because some techniques are not very sensitive to the quality of the optical components.

Another form of diagnostic technique used in shock tubes is to photograph the movement of very small particles which are convected in the flow. In the method developed by Professor J. M. Dewey (University of Victoria, British Columbia, Canada), cigarette smoke is induced to form thin trails across a shock tube, and the variation of all the physical parameters behind an unsteady shock can be determined from an analysis of the trajectories of the smoke particles within the flow. This method compares favourably with others and seems to be slightly better than piezo-electric pressure transducers, for example.

Although the new visualization techniques add further dimensions to flow analysis, the more conventional methods continue to produce important data. This was clearly illustrated by the study of the highly complex structure of the detonation wave described by Dr D. H. Edwards (University of Aberystwyth). From an analysis of schlieren, interferometer and soot-track records he has deduced that although the Chapman–Jouguet model may be adequate for predicting the gross properties of the processes, the extremely intricate wave interactions that occur behind the wave make it impossible to relate detailed structure from one set of conditions to another.

Dr J. H. L. Ranson (Pilkington Bros. Ltd) described the effects of shock propagation through windscreens toughened in certain areas leaving specially selected zones of less tough glass. In practice these shocks might be produced by stones, but in the laboratory small detonators fixed to the windscreen produced the required impact effect. Using a high-speed camera running at 200,000 frames per second it was possible to investigate the reflexion and deflexion of the shocks by the various zones. The intention is to produce windscreens through which there will still be a measure of visibility even after an accident such as that simulated by the detonator.

NEURAL DEVELOPMENT

Visual Stimuli specify Connexions

from our Experimental Psychology Correspondent

ENVIRONMENTAL events can influence the formation of neuronal connexions during development. This is the conclusion of R. M. Gaze, M. J. Keating, G. Székely and L. Beazley (*Proc. Roy. Soc.*, B, **175**, 107; 1970). The connexions made by growing neurones during development and regeneration have long been thought to be determined genetically. It now seems that this genetic determinism, which specifies where neurones make connexions in the visual system of the *Xenopus* toad, is accompanied by a means for bringing neurones together if they receive a similar pattern of input from both eyes simultaneously.

This hypothesis, due to Keating (*J. Physiol.*, **198**, 75*P*; 1968), has been tested by operating on the eyes of embryos before the formation of the retina, or any connexion of the eye with the brain. At this stage, however, the cells destined to develop into the retina were already specified as to their relative positions. In the first type of operation, a developing eye cup was cut in half vertically. The outer (temporal) half was removed and replaced by a nasal half from the opposite eye of another animal. The resulting preparation had one normal and one double-nasal eye. In the second type of operation, one of the larval eyes was rotated by 90 or 180 degrees.

After metamorphosis of the operated animals the projections of the retina onto the brain were mapped, by finding the position of a light in the visual field from which a response could be recorded electrophysiologically in each of a series of standard positions covering the optic tectum (a primary visual region of the brain in amphibia). In the normal visual system of these species there is a direct projection of each eye to the tectum on the other side of the brain (contralateral). There is also a projection from each eye to the tectum on the same side (ipsilateral), but this connexion is made indirectly through the contralateral projection to the other side. A given tectal position thus corresponds to a single point in visual space as seen by both eyes, and these points on the tectal surface provide an orderly map preserving the spatial relationships of the visual field.

Gaze *et al.* confirmed that in animals with one double-nasal eye, the primary (contralateral) projection is systematically altered. Each part of the eye in the new temporal position projected not in the way that a normal temporal retina would but in a manner appropriate to its origin on the nasal side of the eye. In contrast, every part of the indirect ipsilateral projection of the double-nasal eye was appropriate not to its embryological place of origin but to its new position with respect to the visual field.

Results from animals with one rotated eye followed the same kind of pattern. The map of the rotated eye onto the contralateral projection of the tectum was rotated appropriately to the early embryological coordinates of the retina, but inappropriately to the new retinal orientation with respect to the visual field. The ipsilateral projection, however, was not rotated, and was appropriate to the visual field.

In both types of preparation, although the contralateral projection of the normal eye was normal, as expected, the ipsilateral projection was rearranged to fit in with the altered projection of the surgically manipulated eye on the other side. Although the direct contralateral projections of both normal and abnormal eyes seemed to be determined by innate specification according to their original position in the embryo, as far as the indirect ipsilateral connexions were concerned, neurones growing from one tectum to the other appeared to have joined with those directly projecting neurones from the other eye which subserved the same point in visual space. There were thus two ipsilateral connexions in each toad, one from the operated eye with an abnormal first (contralateral) stage and a normal cross-tectal second stage, and another with a normal contralateral stage and abnormal destinations for the fibres of the cross-tectal stage.

Gaze *et al.* claim that "the evidence appears to establish beyond doubt that a functional interaction between the visual inputs from the two eyes, occurring at the tectal level, operates in the establishment of specific neuronal connexions in the ipsilateral visual projection". Any hypothesis of purely genetic determination would predict that neurones subserving the two eyes would come together according to their original embryological position (as happens in the contralateral projection). Instead, for the indirect ipsilateral projection the determining factor is a position in the visual field present during the seeing life of the individual animal. This conclusion seems to indicate that permanent connexions between two neurones can be made on the basis of simultaneous coincidence of input in both. As a principle for understanding development, and as a clue to the possible nature of the neuronal changes underlying learning, this conclusion is of the greatest importance.

There are now over ~~300~~ 500 members of the EM 300 Club...

...five hundred users of the Philips EM 300 Electron Microscope, in 24 countries throughout the world. There's nothing exclusive about this club. Its membership is growing steadily.

But there are some special privileges associated with belonging.... ownership of the most respected high-resolution electron microscope in the world... support of the finest service organisation, backed by the finest research and development team. Best of all is the unusual protection against obsolescence. New improvements and accessories keep coming along. The latest include a new TV display system with image intensifier, new X-ray spectrometer attachment, new pre-pumped air-lock, and new specimen chamber cold trap. Each of these may be retrofit to existing equipment.

If you are already a member of the EM 300 Club, you should take full advantage of your membership by contacting your Philips representative about these new improvements to the EM 300 - and EM 200 as well.

If you're not already a member, you should look into becoming one, don't you think?

Write for our free EM 300 brochure, as a first step.

Interrelations of Some Pituitary Hormones

by

P. J. LOWRY*
A. CHADWICK

Department of Zoology,
University of Leeds

A comparison of the structure of melanocyte stimulating hormone (MSH) of the dogfish with mammalian MSH, adrenocorticotrophin and lipotrophin points to some possible interrelationships and lines of evolution.

At least ten hormones with different functions have been prepared from extracts of mammalian pituitary glands, and they can be divided into groups on the basis of their cytological origin, target organs and tissues and structure and chemistry. Little is known, however, about these aspects of the pituitary hormones of non-mammalian vertebrates[1]. Even the homologies of the different regions of the pituitary gland in different classes of vertebrates are sometimes in doubt and there have been few reports of the structure of the hormones, with the exception of the octapeptides of the neurohypophysis. The chemistry, pharmacology and physiology of the neurohypophysial hormones have been investigated in both mammalian and non-mammalian vertebrates, and this work has been the subject of recent reviews[2-4] in which the relationships between the peptides in different classes of vertebrate have been considered.

The adenohypophysial hormones adrenocorticotrophin and melanocyte stimulating hormone (MSH) have also been widely studied, but their chemical compositions and structures have been determined only for a few species of mammals[5,6]. Lipotrophin, the pituitary hormone responsible for the mobilization of lipids, has been fully described recently in the sheep, ox and pig. It is clearly a member of the same group of polypeptides as the other two hormones[7-9]. The biological property which this group of hormones has in common—the ability to cause the dispersion of melanin granules in the melanophores of certain lower vertebrates—was first described in pituitary gland extracts by Hogben and Winton[10]. Early work was concerned with colour change in amphibians, but it was not long before the same principle was demonstrated in the pituitaries of other vertebrates including mammals. Studies of the melanocyte stimulating hormones of all classes of vertebrates still depend on visible changes in the melanophores of a few species of reptiles and amphibians, for these are the only biological tests available. No function has yet been unequivocally ascribed to the MSH in mammalian pituitary glands[11,12]. In the dogfish, as in amphibians, the skin becomes pallid after the removal of the intermediate lobe of the pituitary and can be darkened again by injecting homologous or heterologous pituitary preparations containing MSH (ref. 13). In bony fishes and reptiles the response is complicated by direct innervation of the melanocytes. There has been some dispute as to whether direct nervous control or a melanin aggregating hormone is involved in the melanocyte response in elasmobranchs, and the evidence was reviewed by Waring[14]. The slow swimming action of the dogfish and its poorly developed escape reaction suggest that an ability to merge with the background must have survival value.

MSH in Dogfish

In spite of much knowledge of the chemistry of the mammalian MSHs, virtually nothing is known about the structure of MSH from lower vertebrates. Such information could throw light on the origin and evolution of the hormone or on its function in the higher vertebrates and so we decided to investigate MSH in an elasmobranch of commercial importance and therefore ready availability—the dogfish *Squalus acanthias*.

We first extracted MSH. The neuro-intermediate lobes from 4,000 pituitary glands were homogenized in ice-cold 1 M acetic acid. Saturation with ammonium sulphate precipitated inactive material and the supernatant was desalted in acetylated dialysis tubing[15] against 1 M acetic acid at 4° C. The freeze-dried extract was subjected to gel filtration at 4° C on 'Sephadex *G*-25'. Monitoring the eluate at 280 nm and testing each fraction for MSH activity by a modification of the method of Burgers[16] revealed a single main peak of extinction coincident with the biological activity. This peak was chromatographed on 'Biogel *P*6' and the aromatic retarding characteristics of this gel brought about further purification. Ion exchange chromatography on carboxymethylcellulose (CMC) separated the active material into two components of different basicity. These were present in similar amounts and had the same specific activity in the assay; they were termed PI and PII. The amino-acid sequences of the two components were determined by standard methods of end group analysis: subtractive Edman procedure, Edman-dansyl procedure[17,18], and digestion with amino-peptidase M and with carboxypeptidases A and B. The peptides were fragmented by digestion with trypsin and by the cyanogen bromide reaction[19], and the products were separated for further analysis using paper electrophoresis[20] and ion exchange chromatography on CMC. The sequences of the two active peptides were found to be identical and closely similar to mammalian α-MSH (Table 1: 2, 4, 5). A persistent tyrosine contaminant at the level of 20 per cent of the other amino-acids was noted. (This work will be reported in detail later.)

Assay showed the specific activity of dogfish peptides PI and PII to be lower than that of mammalian MSH. This is in agreement with the results obtained with a synthetic peptide of similar composition[21]. Although PI could be an artefact introduced during extraction, we think that this is unlikely in the mild conditions used. The presence of PI and PII in similar proportions may simply demonstrate the parallel occurrence of two active pituitary peptides or may suggest that amidation of the COOH terminus confers some protection on the peptide after it has been released from the gland. The melanin dispersing ability of these preparations in elasmobranchs was confirmed by injecting the pure peptides into pale

---

skate from which the neuro-intermediate lobe of the pituitary had been removed. The fish rapidly darkened.

α-MSH and β-MSH were also isolated from ox pituitaries by the chromatographic methods we have described. The fractionation patterns of α-MSH and dogfish MSH were in agreement with their structural similarities, but no counterpart for β-MSH was found and we concluded that it is absent from the dogfish pituitary gland. Biologically active peptides with chromatographic and electrophoretic characteristics in common with β-MSH have recently been reported in selachians, holocephalans and teleosteans, but these studies were not carried out on pure peptides[22]. Geschwind[6] reported the presence in the pituitary gland of the teleost *Gadus* of two biologically active components with electrophoretic mobilities similar to mammalian α-MSH and β-MSH, the former being the more abundant. Burgers[23] described electrophoretic separation of three biologically active components from pituitary extracts of the amphibian *Rana*—frog—and the reptile *Anolis*, none of which seemed to be identical with the mammalian hormones.

Several Types of MSH

The presence in a single pituitary of several hormones with melanocyte-stimulating activity (up to seven in mammals if the reported occurrence of two corticotrophins and two β-MSHs is a general phenomenon) raises the question of whether they exist *in vivo* as separate entities, or result from the partial breakdown of parent molecules during preparative procedures. The species differences in particular hormones, coupled with the lack of knowledge of a complete series of amino-acid sequences for all the hormones of any one species, make it impossible to decide whether this is possible, but a comparison of the available sequences is nevertheless interesting. The common element is the heptapeptide "core": methionyl glutamyl histidyl, phenylalanyl arginyl tryptophanyl glycine, a sequence which by itself has considerable MSH activity (Table 2). The pentapeptide his.phe.arg.trp.gly. has also been reported to have MSH activity[20], but this may be too low to have any biological significance. The differences between the hormones consist partly of substitutions of one amino-acid for another, which is also the usual form of species differences in a given hormone, and partly of the lengthening of the amino-acid chain on either or both sides of the core. The core is roughly in the middle in the short chains of α-MSH and β-MSH and at the amino end of the ACTH molecule. β-MSH is an uncoiled polypeptide chain and ACTH is a random coil with no secondary or tertiary structure[24], although recent reports of the spatial conformation of the insulin molecule show that even a relatively small peptide can have a complex tertiary structure[25].

Table 2. MELANOCYTE STIMULATING ACTIVITY OF NATURALLY OCCURRING AND SYNTHETIC PEPTIDES

No.	Peptide	Relative potency
1	Corticotrophin	1×10^4
2	α-MSH	1×10^6
3	Synthetic	1×10^4
4	Dogfish MSH PI	1×10^4
5	Dogfish MSH PII	1×10^4
6	Synthetic	1×10^3
7	Synthetic	1
8	Ovine β-ser^2-MSH	1×10^5
9	Human β-MSH	1×10^5
10	Ovine γ-LPH	1×10^3
11	Ovine β-LPH	1×10^3

The numbers refer to sequences listed in Table 1. It is doubtful whether more precise estimates of potency are useful in view of the widely different methods of assay which have been used in obtaining the figures quoted.

This table shows approximate potency relative to the shortest synthetic peptide with MSH activity.

Comparison of Sequences

The position of the core relative to the terminal amino-acids suggests that certain linkages in conjectural parent molecules are more readily broken than others. The peptides fall naturally into two divisions, the members of each having common points of similarity and difference in comparison with members of the other division. Thus in Table 1 peptides 1 to 5 form one group, including the naturally occurring hormones ACTH, α-MSH and the dogfish MSHs PI and PII; and peptides 8 to 11 form a second group which includes β-MSH, β-LPH and γ-LPH. The peptides in the first group have the amino-acid serine immediately before the common heptapeptide and lysine immediately after, a situation which is exactly reversed in the second group. In both groups the next residue at the carboxyl end is proline and no species differences have been found at this point. The carboxyl ends of the second group of peptides are longer than in the first group, except for ACTH, and are almost identical for the whole of β-MSH and γ-LPH and up to residue 58 in β-LPH. In ACTH the amino-acid chain is extended considerably beyond the common element and the lysine and arginine at positions 16 and 17 in corticotrophin are found in β-LPH in the same place relative to the core, that is, positions 59 and 60. The dogfish MSHs, α-MSH and corticotrophin are all similar on the amino side of the core and the chain is shorter than in the second group of peptides. β-ser^2-MSH, present in the sheep, is identical with the sequence 41 to 58 in sheep γ-LPH and sheep β-LPH, and all the second group peptides are closely similar over the first six to ten residues on this side of the core. Although human β-MSH has two amino-acid substitutions in this region which are not found in non-primate β-MSHs, the four residues of its extended NH_2 terminus are identical with those in the same positions relative to the core in the LPHs isolated from the sheep (Table 1).

The isoelectric points of the β-MSHs studied so far lie between *p*H 5·5 and 7·0. The charge on the hormone at physiological *p*H varies according to the amino-acid substitutions present. Serine or glutamic acid may be present at position 2 in ovine β-MSH, affecting not only its charge but possibly also its potency, as β-glu^2-MSH is reported to be more than twice as potent as β-ser^2-MSH or the similarly charged equine β-glu^2, arg^{16}-MSH when assayed *in vitro*[6]. α-MSH is more basic, having an isoelectric point between *p*H 10·5 and 11·0. Burgers[23] reported that the major biologically active MSH component in codfish pituitary glands has an electrophoretic mobility consistent with that of α-MSH, and Geschwind[6] reported that the minor component was probably more basic than β-glu^2-MSH. The isoelectric points of the dogfish MSH peptides were calculated to lie between *p*H 10·5 and 11·5.

Structure and Activity

Table 2 shows the approximate relative potencies of the hormones and of some synthetic peptides. (This subject has been reviewed by Harris[26] and Geschwind[6].) With regard to the effects of structural differences, it is sufficient to point out that many changes which can be construed as protecting the core from enzymatic breakdown enhance biological potency. For example, acetylation of the NH_2 terminus of a synthetic peptide which is closely similar to dogfish MSH (No. 3 in Table 1) increased its MSH activity twenty-five-fold[21]. α-MSH has the greatest specific activity of all naturally occurring peptides and a lengthening of the polypeptide chain at either end, as in ACTH, on the one hand, and β-MSH on the other, results in a reduction in biological potency. Nevertheless it must be remembered that biological potencies can vary widely for the same molecule measured *in vivo* and *in vitro*, and that because very little is known about how MSH acts at the cellular level there remains the possibility that some differences in potency may be attributable to different effects on the target organ.

At the other end of the spectrum of biological activities is the stimulation of the adrenal cortex, which is primarily the function of ACTH and only exhibited to a much smaller extent by LPH and MSH. Because it is known that a synthetic peptide identical with the first twenty-three residues of ACTH possesses full biological potency, residues 24–39 cannot be one of the molecular groupings responsible for this action. It is interesting that interspecies variation in this hormone, so far investigated only in mammals, is found in residues 25–32. And so it seems that residues 14–23, probably acting in conjunction with residues 1–13, are responsible for the adrenocorticotrophic effects. Synthetic peptides identical with residues 1–17 and 1–19 possess some adrenocorticotrophic activity[24]. The dipeptide lys.arg. occurring at positions 16 and 17 in ACTH is also found at positions 59 and 60 in β-LPH and might be responsible for the low ACTH activity reported for the latter hormone[6]. However, γ-LPH, which stops short at residue 58, also has significant corticotrophic activity, as does MSH. The possibility that some of the preparations were contaminated with small amounts of ACTH and that this is at least in part responsible for the results cannot be ruled out. The lipolytic potency of the hormones, as exhibited in adipose tissue of rat and rabbit, is strongest in γ-LPH and β-LPH, although both ACTH and MSH seem to possess some activity[7]. At this time it is impossible to indicate any particular groupings responsible for this action. The effect is presumably due to changes in the concentration of tissue lipase, which is also affected by many other agents including growth hormone, glucagon and the catecholamines. The mechanism responsible is not understood at all. LPH has not so far been identified in the pituitaries of non-mammalian species.

The physiology and chemistry of MSH, ACTH and LPH encourage speculation on several evolutionary questions. Although elasmobranchs are not in the direct line of vertebrate ascent, the close similarity between dogfish MSH and α-MSH on the one hand, and between α-MSH and mammalian ACTH on the other, indicates certain features that would be expected in the ACTH of elasmobranchs, which has been found in the dogfish[27]. A foreshortened amino terminus of H-ser. or possibly H-tyr.-ser. is likely and a met.-val. substitution might be expected at residue 11. A shorter carboxyl end is also possible in view of the ACTH activity of the synthetic analogues. Other points of more general interest are, first, is α-MSH more primitive than β-MSH ?; second, what are the primitive functions and inter-relationships of the peptides with MSH activity ?; and third, how has MSH evolved ?

Is α-MSH Primitive ?

α-MSH is not only the most highly potent of the MSHs in causing the dispersion of melanin, it is also the shorter of the two naturally occurring forms. Its high potency probably results from the possession of an acetyl.ser.tyr.ser. terminal tripeptide which protects the biologically active core from enzymatic degradation and yet does not "bury" it further inside the molecule than is necessary for optimum effectiveness. The high potency of α-MSH, coupled with the fact that it is found unchanged in all mammals so far investigated, suggests that it may be the more primitive melanin dispersing hormone. Our work on dogfish MSH strongly supports this concept. Not only is the dogfish MSH we isolated basically similar to α-MSH, it is actually two residues shorter, which suggests primitiveness. It is the shortest MSH so far extracted as the principal biologically active peptide from any organism. The relationship of the serine and lysine on either side of the heptapeptide core is of the α-MSH type and the tyrosine contaminant observed, coupled with the end group and sequence analysis results, suggests that a certain proportion of molecules may have the sequence tyr.ser.met. and so on. At the carboxyl end there is a simple substitution of methionine for valine.

There can be little doubt of the common origin of α-MSH and dogfish MSH—one form of the latter is even amidated at its carboxyl terminus. But our procedures failed to demonstrate the presence of any β-MSH-like peptides in dogfish pituitaries although both α-MSH and β-MSH were clearly demonstrable in extracts of ox pituitaries using the same preparative methods. Whether or not this observation also indicates the primitiveness of α-MSH awaits further elucidation of the fish MSH peptides mentioned earlier.

The close similarity of the β-MSHs to the LPHs and the absence of blocking radicles at the NH_2 and COOH termini suggest that β-MSH might result from partial degradation of LPH. This idea is supported by the fact that the β-MSHs end with aspartic acid, for this amino-acid is in the same position relative to the heptapeptide core, that is, at position 58, in both β-LPH and γ-LPH. γ-LPH

R360

is identical to a subfraction of β-LPH, cleaved after residue 58, which suggests that the asp.-lys. bond at this point might be particularly labile or susceptible to specific enzyme cleavage. A lys.-asp. cleavage at the other end of the peptide could also account for all the non-primate β-MSHs so far reported, by the splitting of their respective lipotrophins if these exist with the corresponding specific amino-acid substitutions. By the same argument the extra tetrapeptide at the NH_2 terminus of human β-MSH would result either from the greater lability of bond 36–37 in human LPH or the existence of a different enzyme system. Cytological evidence regarding the pituitary origin of the two hormones does not, however, support this concept and more LPH sequences are needed before any conclusion can be drawn.

Primitive MSH Peptides

The cyclostomes, the most primitive living vertebrates, can change colour in the wild, and hypophysectomy of the lamprey results in the aggregation of melanin so that the animal becomes pale. Thus the ability to disperse melanin is of great antiquity in vertebrates. Protective coloration and an ability to change colour to merge with the background probably had survival value in the sluggish heavily armoured agnathan ancestors of vertebrates. It must be pointed out that adrenal cortex-like tissue is present in cyclostomes and that mobilization and depletion of body fat reserves also occur at certain seasons in many fishes. ACTH function and LPH function may already be established in the primitive vertebrates. But although the chemistry of the principles responsible for these activities in primitive forms awaits elucidation, the available information supports the hypothesis that dispersion of melanin is the most primitive attribute of the three. Thus the peptide "core" common to all has substantial MSH activity but must be deficient in the other properties. Progressive extensions and substitutions may have been responsible for the evolution of the two divergent groups, ACTH and α-MSH on the one hand, and β-MSH and LPH on the other. A second possible alternative is the occurrence of a large molecule with all three types of activity. The level of secretion and its duration could determine the stimulation of the appropriate target tissue.

Although the role of MSH in mammals is not fully understood, the preservation of the heptapeptide core, coupled with the apparently random variations at certain other sites in the mammalian β-MSHs, suggests that the core sequence is important in the molecule itself and that the molecule is important to the animal. It seems inconceivable that the genetic code for this particular sequence could have been derived and preserved on more than one occasion in a group of obviously related hormones. It is perhaps significant that melanocytes originate in the cells of the neural crest of the embryo and that neurological effects have been reported for both MSH and ACTH in experiments on mammals[28,29].

The Question of Evolution

If α-MSH and dogfish MSH derive from a biologically active molecule present in a common ancestor, it probably had either methionine or valine at the COOH terminus. The substitution of one hydrophobic amino-acid for another would not affect biological potency. A single mutational nucleotide base change is sufficient to account for the substitution. The amidation of the COOH terminus of α-MSH is also found in a proportion of dogfish MSH and must result in the latter in differing degrees of susceptibility to carboxypeptidases. On the amino side of the heptapeptide core serine is present in both cases, and in a high proportion of dogfish MSH it is at the NH_2 terminus. But, as we have noted, as much as 20 per cent of the dogfish hormone may have the sequence H tyr.ser. met. . . ., which clearly approaches the Acetyl.ser.tyr.ser. met. . . . of α-MSH. Whether or not the situation in the present day dogfish represents an early stage in the evolution of the mammalian peptide, the primitive elasmobranchs diverging as they did more than 300 million years ago from the line of evolution leading to mammals, we know that elongation of this peptide brings about a progressive increase in potency which selection might favour. However, although acetylation of dogfish MSH would bring about a twenty-five-fold increase in potency, this has apparently not happened, which suggests that the melanocyte physiology in the dogfish may require a more labile hormone.

If evolutionary changes leading to increase in the length of peptide chains occur by mutational elongation of the specific DNA, the addition of tyrosine at the NH_2 terminus of this peptide could be accounted for by the replication of the appropriate serine codon followed by a single base substitution, or by a defect in genetic duplication which resulted in an initial "out of phase" rendering of the code, followed at once by the restart of the correct sequence. It is easier to derive the first stages of the β-MSH/LPH sequence from the heptapeptide core than the α-MSH/ACTH pattern. Thus duplications of the appropriate codons followed by single base substitutions will yield lysine or arginine but not serine from methionine at the NH_2 terminus and serine but not lysine from glycine at the COOH terminus.

New Hominid Remains and Early Artefacts from Northern Kenya

Five hominid specimens, including two well preserved crania, early artefacts and a rich collection of vertebrates have been recovered from Plio-Pleistocene deposits near Lake Rudolf. Some of the artefacts were located *in situ* in a horizon that has since been reliably dated with a new isotopic technique at 2·61±0·26 million years. They constitute the oldest known *in situ* dated unequivocal artefacts.

Fauna and Artefacts from a New Plio-Pleistocene Locality near Lake Rudolf in Kenya

In 1968 the National Museums of Kenya organized a three month expedition into the area east of Lake Rudolf in northern Kenya (see Fig. 1), and a second three months were spent there in the summer of 1969. Both expeditions were greatly assisted by the Kenya Government.

Before 1968 no expedition had penetrated the region and little was known about its geology. Aerial reconnaissance in 1967 had, however, revealed extensive sediments, and so plans were made to survey the area in more detail. Miss A. K. Behrensmeyer of Harvard University joined the expedition in 1969 and her preliminary report on the geology of the region east of the Koobi Fora peninsula follows.

Fossil vertebrates are abundant throughout the sediments in the Koobi Fora area. A small collection was made and this is now housed in the National Museum, Nairobi, where more detailed studies are in progress. The collection included five hominid specimens. The brief description here of this material is to be followed later by a more detailed report by Professor J. Mungai of the University College, Nairobi. Artefacts were recovered from the surface in several places and at one site they were located *in situ* in a horizon that has since been dated by Fitch and Miller, using K–Ar techniques, at 2·61±0·62 m.y. which is Plio-Pleistocene age (see p. 226 of this issue). A full description of the artefacts is given by Dr Mary Leakey in an accompanying letter.

The vertebrate material has some similarities with that collected in the Omo Valley by the 1967 International Palaeontological Expedition[1], and detailed comparisons between the collections should prove interesting. The fauna includes the fish *Clarias* and *Polypterus* and the reptiles *Crocodilus niloticus*, *Euthecodon brumpti* and chelonians. Several genera and species of mammal were found, including some that are abundant in the Omo Valley beds. *Elephas* cf. *recki* is the most common proboscidean, *Deinotherium* being rare. Specimens of a very primitive elephant that closely resembles the material from the Lothagam Hill site near Lake Rudolf[2] were recovered from site *KF–I* and this material is consistent with the occurrence of the suid *Nyanzachoerus* at the same level. *Equus* and *Stylohipparion* are both present although they are not common. *Ceratotherium simum efficax* is better represented than *Diceros bicornis*. Several species of Hippopotamidae were collected, including both the tetraprotodont and hexaprotodont varieties. Suidae are common, those identified being *Nyanzachoerus* sp. (from *KF–I*), *Mesochoerus limnetes*, *Pronotochoerus*, *Notochoerus*, *Afrochoerus* and *Gerontochoerus*. *Mesochoerus limnetes* is represented by two complete and well preserved skulls. Giraffidae are rare and only a few fragments, possibly *Giraffa gracilis*, *Libytherium* and *Okapia*, were collected. Alcelaphini, Antilopini, Reduncini and Tragelaphini are common. At site *KF–I*, a bovine skull with horn cores resembling the Eurasian *Leptobos* was found. Another bovid of particular interest resembles *Lunatoceras* material from southern Africa. It is represented by one skull with horn cores and a single horn core.

Carnivora are quite common but most of the material is very fragmentary. A machairodont cranium with one side of the mandible intact was collected, but specific identification is not yet possible. *Felis* and *Panthera* are represented in the collection and one mandibular fragment of *Crocuta* was recovered. We have one representative of Mustelidae and this is very similar to, although larger than, the present day genus *Mellivora*.

Primate material is common in certain localities and 127 specimens were collected including some post-cranial remains. *Papio*, *Simopithecus*, *Colobus*, *Cercopithecus* and one specimen of *Galago* have been identified in a preliminary examination of the collection. A more detailed description of this material will be given by Dr Meave G. Epps and myself in a paper on the classification of the East African cercopithecoids which we are currently preparing.

Among the five hominid specimens are two well preserved and nearly complete crania. One of the crania (*FS*–158) resembles *Australopithecus boisei* from Olduvai. The specimen (see Fig. 2) lacks teeth but is otherwise complete. It was recovered by Dr Epps and myself from the lower part of *KF–IIA*, a horizon below the tuff that provided the isotopic date of 2·61±0·26 m.y. Three

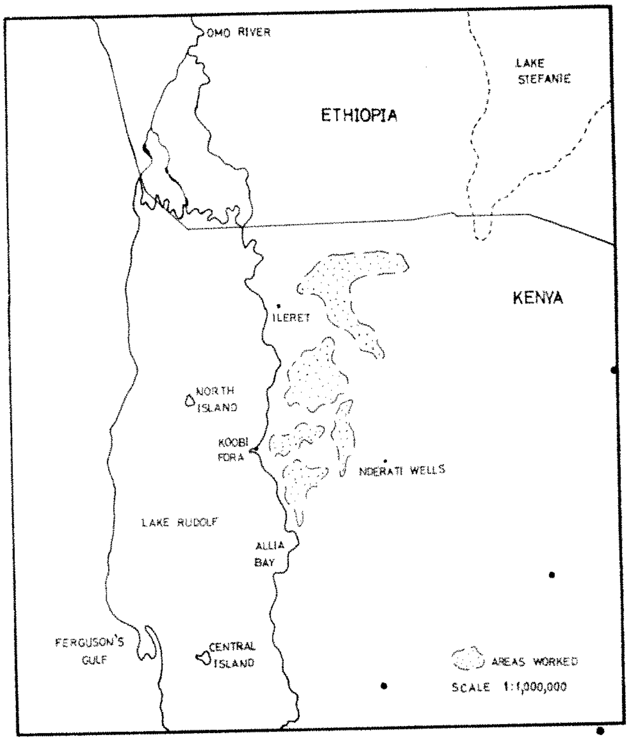

Fig. 1. Map showing the extent of the investigations in the Koobi Fora area, east of Lake Rudolf.

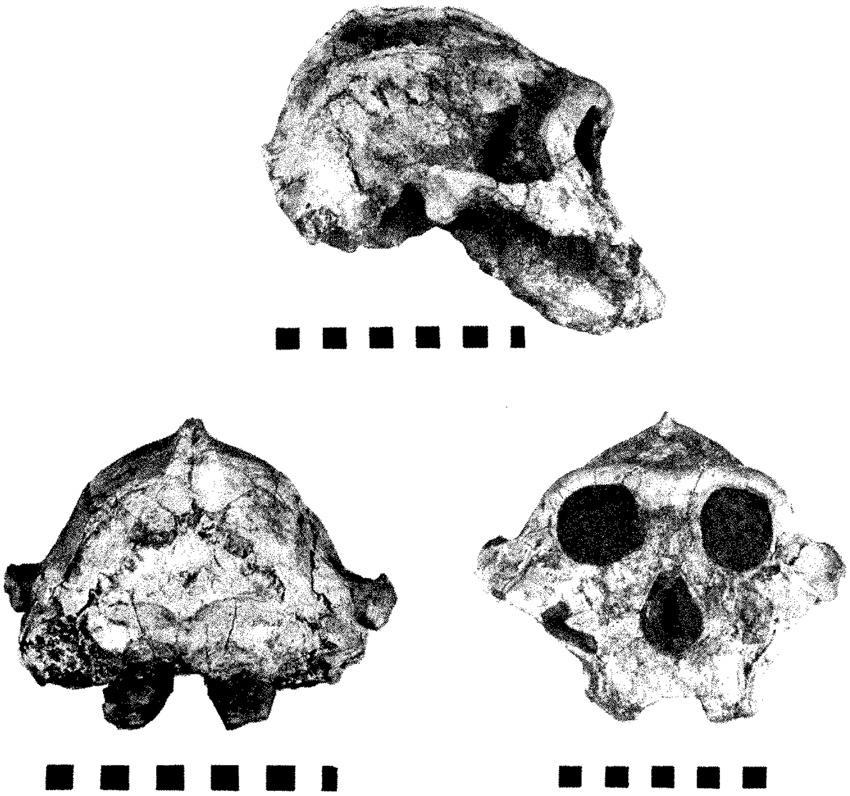

Fig. 2. Various views of *FS*–158—*Australopithecus boisei.*

other specimens, two mandibular fragments and an extremely weathered maxilla, were collected during the 1968 season, and these with *FS*–158 will be described by Professor Mungai. The four specimens may be conspecific. The second cranium (*FS*–210) was collected from a site approximately one mile north of the site where *FS*–158 was found, and was likewise from the lower part of *KF–IIA*. The specimen is fragmentary and only the basi-occipital region and the parietals are present (see Fig. 3). Its morphology contrasts markedly with ***Australopithecus boisei*** and it probably is either a gracile species of *Australopithecus* or else a very early representative of *Homo*; the latter possibility is considered more likely from the evidence of the occipital region, the temporals and the tympanic plate. It is hoped that further material will be recovered this summer. The discovery of *FS*–210 which seems to be distinct from the australopithecine *FS*–158 is consistent with the evidence from Omo and Olduvai in so far as more than one form of early hominid has been reported from both these East African localities. In view of the generally accepted opinion that *A. boisei* was not a toolmaker, the discovery of artefacts in the Koobi Fora deposits adds support to the evidence from the fossil material that there were two different representatives of hominids in the area we investigated.

All the artefact sites occur in the upper part of the tuff in *KF–IIA* and, in most cases, bone fragments were found in association with a few flakes and the occasional finished implement. In view of the significance of these living sites, I excavated a small trial step trench, 15 feet long by 4 feet wide at site *KBS*, to see if I could determine the exact stratigraphic position of the artefacts. Five flakes and fourteen bone fragments were uncovered and collected. The depth of the trench through the three steps was just less than 1 m and the consolidated and undisturbed nature of the matrix above the specimens confirmed that the material was *in situ*. The flakes that were recovered from the excavation were struck from the same raw material as the specimens lying on the surface of the site. The discovery of artefacts *in situ* in a horizon that has been dated at 2·61 ± 0·26 m.y. is very significant and further investigations in the Koobi Fora area are planned for this coming season.

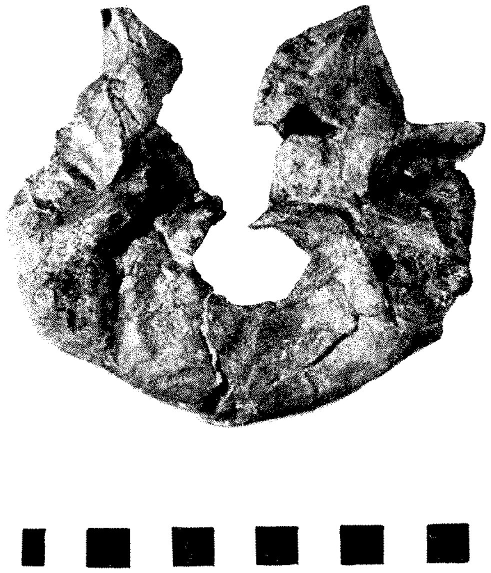

Fig. 3. Basal view of *FS*–210.

The National Geographic Society, Washington DC, provided generous financial support for the expeditions.

Preliminary Geological Interpretation of a New Hominid Site in the Lake Rudolf Basin

A GEOLOGICAL reconnaissance of an area that included approximately 650 square miles between 3° 40′ and 4° 20′ north latitude and from the east shore of Lake Rudolf to about 36° 25′ east longitude was carried out during 1969. Within this area, a more detailed study was made of the exposures along an erosional escarpment east of the Koobi Fora peninsula (see Fig. 1 of previous report). This provided a shallow east–west cross-section of part of the eastern border of the Lake Rudolf Basin.

The sedimentary rocks of the region are generally low-lying, with a maximum relief of about 100 m above the present lake level, which is 370 m above sea level[1]. The deposits, of undetermined thickness but probably exceeding 300 m, occur throughout the area, and the oldest identified so far contain an early Pleistocene mammalian fauna. Overlying them unconformably are horizontal, sub-recent lake sediments. An extensive area of basalt flows and intrusions occurs in a broad ridge south-east of Ileret that roughly divides the sedimentary exposures into northern and southern parts. No flows were observed interbedded with the Pleistocene deposits, and the relationship of the volcanics to the fossiliferous sediments has not yet been clarified. Lenses of bentonitic ash-fall and water-deposited tuff occur throughout the sedimentary sequence. Several of these contain fresh pumice suitable for K–Ar dating.

The structural characteristics of the area seem to be closely associated with the tectonic setting of the East African Rift System[2]. A fault zone in the southern part cuts across the exposures of sedimentary rocks at Koobi Fora. There are no continuous major faults, but rather series of parallel fractures 0·5 to 3 miles long. These are generally oriented north–south, with individual throws of less than 50 m. All faulting seems normal, and the downthrown sides are usually on the west. The area within about 8 miles of the lake is the most heavily faulted, and parts of the section are often repeated or missing. Here the sediments are also folded in a broad anticline with a roughly east–west axis and an eastward plunge. The thickest continuous section, 250 to 300 m, is exposed in the anticline. The lower 100 m of this can be traced towards the east, where the bedding becomes horizontal, and can also be picked up north of the basalt ridge. In both places the upper part of the section is missing due to erosion or non-deposition.

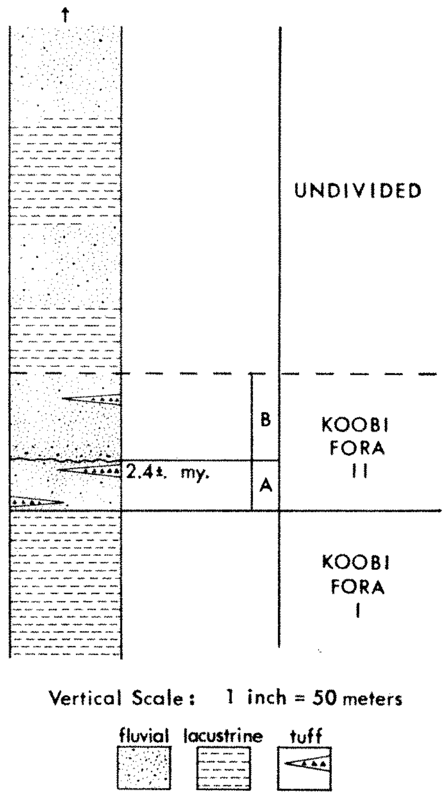

Fig. 2. Generalized stratigraphic divisions of the lower part of the Pleistocene sediments exposed at Koobi Fora. The predominant environment of deposition is indicated by the lithological symbols.

The Pleistocene sediments range from coarse sands and pebble conglomerates to fine silts and clays. Particle size, sedimentary structures, and the included fauna indicate deposition in at least two major types of environments; fluvial and lacustrine. A distinct lacustrine to fluvial transition occurs in the lower part of the section. Thinly bedded limonitic clays and sands are overlain by non-limonitic sandy clays, quartz and limonite pebble conglomerates and coarse cross-bedded sandstones. The change in lithology is easily recognizable and serves as the boundary between the lower lacustrine unit, designated as Koobi Fora I (*KF–I*), and the overlying fluvial unit,

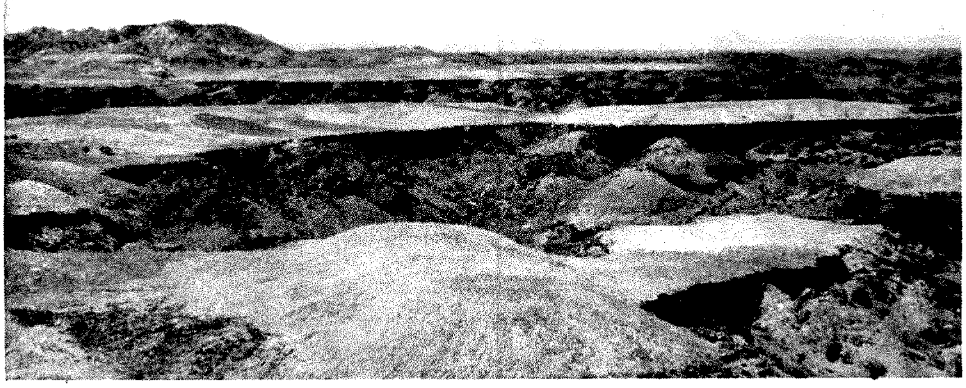

Fig. 1. Pleistocene exposures about 15 miles ENE of the Koobi Fora peninsula, looking east, with the mountains Shin and Nderati in the distant background. The prominent resistant bed marks the boundary between *KF–I* (lower, darker deposits) and *KF–II* (overlying, light-coloured deposits).

Koobi Fora II (*KF–II*) (see Figs. 1 and 2). *KF–I* is characterized by a predominantly fish and mollusc fauna, while *KF–II* is rich in mammals. *KF–II* is divided into a lower "*A*" and an upper "*B*" in the eastern part of the area by an erosional unconformity some 20 m above the base of the unit. The tuff bed containing stone tools *in situ* occurs high in *KF–IIA*. A preliminary evaluation of the fauna indicates that the time break represented by the unconformity is probably not significant. The lithology and stratigraphic sequences in *KF–II* are laterally persistent. On the basis of the almost identical stratigraphic successions and lithologies north and south of the basalt ridge, the sites of the hominid skull finds in the northern part are provisionally placed in *KF–IIA*.

The upper boundary of *KF–II* is tentatively set at the top of coarse quartz sandstones and conglomerates which cap the horizontal section east of the anticline. The thick section overlying *KF–II* has been studied only in the anticline and is not yet subdivided. It includes several alternating phases of coarse and fine sediments. Vertebrate and invertebrate fossils occur throughout, with mammalian remains more common in the coarser deposits.

Radioisotopic Age Determinations of Lake Rudolf Artefact Site

SAMPLES of a volcanic tuff (Leakey *IA*) and of pumice lumps in a calcareous matrix (Leakey *II*) were sent to us by Mr Richard Leakey in July 1969 for an age determination feasibility study. Even if samples of pyroclastic rocks are completely fresh and otherwise suitable for potassium-argon age determination a number of specific additional sources of error may be present[1]. One of the most intractable of these is the possible presence of extraneous argon derived from inclusions of pre-existing rocks. Preliminary petrographic examination of the tuff sample revealed it to be a crystal–vitric–tuff rich in small pieces of pumice and minute crystal fragments set in a matrix of devitrifying volcanic dust. While much of this pyroclastic material was obviously juvenile, the presence of microcline suggested possible contamination from the wall rocks of the vent. The fine grain-size prevented effective separation of juvenile and possibly non-juvenile components, and an exploratory conventional total rock K–Ar age determination was made finally on the washed and mixed 30/50 mesh fraction of the crushed sample.

Six potassium oxide measurements were made by flame photometry and an average value calculated. Three independent argon isotope analyses were undertaken. Argon extractions and purifications were carried out in the manner described by J. A. M. and Brown[2]; isotope ratios were measured using an omegatron-type mass spectrometer[3]. Enriched argon-38 was used as an internal standard (spike). Errors in radiogenic argon volume arising from uncertainties in the isotopic ratios of the argon sample and spike volume, together with those introduced in the determination of potassium oxide content, are combined. The analytical error in millions of years associated with each separate age determination is calculated according to the method set out by us[4]. The results of these age determinations are given in Table 1. From these results it was clear that an extraneous argon age discrepancy was present, and that it would only be possible to date this tuff by careful extraction of undoubtedly juvenile components for analysis. The pumice lumps (Leakey *II*) would have been suitable if fresh, but on examination they were found to be intensively calcified. Minute sanidine inclusions in the pumice were promising, however, and in reporting the results of this feasibility study we suggested that a search be made of the tuff exposures in the field for (*a*) less calcified pumice lumps, and (*b*) sanidine phenocrysts that could be conveniently separated.

Table 1. ANALYTICAL RESULTS OF WHOLE ROCK TOTAL DEGASSING CONVENTIONAL K–Ar AGE DETERMINATIONS ON THE TUFF FROM *KF-IIA*

Sample	K_2O (per cent)	Atmospheric contamination (per cent)	v/m	Apparent age and error (m.y.)
Volcanic tuff	1·79	62·7	$1·37 \times 10^{-2}$	219 ± 7
(Leakey *IA*)	1·79	63·4	$1·40 \times 10^{-2}$	223 ± 7
	1·79	62·0	$1·39 \times 10^{-2}$	221 ± 7

$\lambda e = 0·584 \times 10^{-10}$ yr^{-1}; $\lambda\beta = 4·72 \times 10^{-10}$ yr^{-1}.
v/m = volume of radiogenic argon-40 (mm^3 NTP) per g of sample.

Further samples were received from East Africa in August 1969 and consisted of pumice lumps (Leakey *IB1*) and a collection of feldspar phenocrysts (Leakey *IB2*) separated from the tuff. The new pumice lumps, although strongly calcified in part, were considerably fresher than those in sample Leakey *II* and contained numerous fresh microphenocrysts of sanidine and aegerine–augite. The separated crystals were mostly of fresh sanidine, but did include a few aegerine–augite and composite feldspar–pyroxene–iron ore grains. Complete freedom from argon loss discrepancy cannot be expected at a site where carbonates have been so active in replacing volcanic glass, and in view of cracks observed in the separated feldspar crystals that may have occurred during explosive eruption, argon losses from the crystal fraction must be expected in addition to the possibility of extraneous argon errors arising from an admixture of non-juvenile crystals. Two exploratory conventional K–Ar age determinations were made to determine whether or not more detailed work on these new samples would be advantageous. One of these exploratory analyses was made on the core of a pumice lump, the other on the remainder of the crystal fraction after a number of the largest, most homogeneous and uncontaminated feldspar crystals had been picked out and held in reserve. These conventional analyses were carried out in a similar manner to that outlined above, and the results are given in Table 2.

Table 2. ANALYTICAL RESULTS OF EXPLORATORY CONVENTIONAL K–Ar AGE DETERMINATIONS ON FURTHER SAMPLES FROM THE TUFF FROM *KF-IIA*

Sample	Method	K_2O (per cent)	Atmospheric contamination (per cent)	v/m	Apparent age and error (m.y.)	Average apparent age and error (m.y.)
Leakey *IB1*	Whole	0·70	99·6	$8·49 \times 10^{-5}$	3·63 ± 2·1	
pumice	rock	0·70	91·1	$5·61 \times 10^{-5}$	2·40 ± 1·0	3·02 ± 1·6
Leakey *IB2*	"Feld-	6·04	81·2	$4·79 \times 10^{-4}$	2·38 ± 0·3	
crystals	spar"	6·04	80·5	$4·76 \times 10^{-4}$	2·36 ± 0·3	2·37 ± 0·3

$\lambda e = 0·584 \times 10^{-10}$ yr^{-1}; $\lambda\beta = 4·72 \times 10^{-10}$ yr^{-1}.
v/m = volume of radiogenic argon-40 (mm^3 NTP) per g of sample.

The two exploratory conventional age determinations were most encouraging. It was virtually certain that the pumice was juvenile and very likely that most, if not all, of the individual phenocrysts collected from the tuff were juvenile also. The proportionally large experimental error quoted with the apparent age from the pumice sample results from its low potassium content and the high value of atmospheric contamination. At this stage it was apparent that for satisfactory dating of the tuff horizon answers were required for the following three questions: (i) was the crystal fraction (Leakey *IB2*) entirely juvenile in origin ? (ii) were any argon losses or extraneous (that is to say, inherited or excess) argon discrepancies present ? and (iii) could the experimental errors be reduced ? In order to find answers to these questions two total degassing $^{40}Ar/^{39}Ar$ and two $^{40}Ar/^{39}Ar$ age spectra age determination analyses were undertaken. Description of the theory and practice of $^{40}Ar/^{39}Ar$ age determination can be found in Mitchell[5], Dunham *et al.*[6] and F. J. F. *et al.*[7]. $^{40}Ar/^{39}Ar$

geochronometry is based on the conversion of a portion of the natural isotope potassium-39 present in a rock or mineral sample to the artificial radioisotope argon-39 by neutron irradiation. The argon-39 yield for a particular neutron dose is proportional to the potassium content of the sample and a value for the constant of proportionality (J) can be derived from the argon-39 yield in standard samples irradiated by the same neutron dose. After an appropriate irradiation, measurement of the argon isotope ratios present in the sample and standard using a suitable high resolution mass spectrometer is all that is necessary for complete total degassing geochronometric analysis. The mass of the sample or standard does not enter into the calculation. Very small and/or inhomogeneous samples and samples of extremely low potassium content can be dated by this method.

^{40}Ar/^{39}Ar age spectrum geochronometry is a development of the ^{40}Ar/^{39}Ar dating technique in which the isotopic composition of the gas being released from an irradiated sample of the rock or mineral is analysed repeatedly over a series of heating steps towards complete fusion. When a rock or mineral sample of uniform age is analysed by this method a very accurate multipoint K–Ar isochron age is obtained. When a rock or mineral sample of mixed age is analysed by this method an "age spectrum" is obtained. This method can be a very powerful geochronological tool. It depends for its success on the fact that there are some argon locales in minerals from which argon can only be driven by extreme stimuli. Thus, if suitable material is chosen and the less tightly held argon removed first, it becomes possible to date the remaining "old" radiogenic argon by itself and to obtain some idea of the early history or crystallization date of the rock or mineral concerned. In practice, this technique frequently produces an age spectrum which can be directly related to the geological history of the rock and can be used to elucidate inherited and/or excess argon discrepancy. The results of the ^{40}Ar/^{39}Ar analyses undertaken on the second batch of samples from the *KF-IIA* tuff are given in Table 3.

Table 3. ANALYTICAL DATA FOR ^{40}Ar/^{39}Ar AGE DETERMINATIONS

(*a*) Total degassing ^{40}Ar/^{39}Ar age determinations

The addition of the four ^{40}Ar/^{39}Ar age determinations to the conventional analyses already made enabled the three questions formulated earlier to be answered.

(i) Juvenile origin of the separated feldspar crystals. Repetition of apparent ages identical within the experimental errors from three different samples of the phenocrystic crystal fraction (that is, 2·37 ± 0·3 m.y. (conventional K–Ar); 2·64 ± 0·29 m.y. (total degassing ^{40}Ar/^{39}Ar) and a plateau age of 2·61 ± 0·26 m.y. (^{40}Ar/^{39}Ar age spectrum)) strongly suggests that this crystal fraction is homogeneously juvenile. When this coincidence is considered in relation to the three independent ages obtained from the pumice (that is, 3·02 ± 1·6 m.y. (conventional K–Ar); 3·45 ± 1·2 m.y. (total degassing ^{40}Ar/^{39}Ar) and 2·5 ± 0·5 m.y. (step heating ^{40}Ar/^{39}Ar): regarded as the best age for the pumice, see below), then it becomes almost certain that both the sanidine phenocryst fraction and the pumice lumps are entirely juvenile and are the products of the same volcanic eruptive phase. Inherited argon errors, such as were present in the analysis of the total tuff (Leakey *IA*), are therefore not present in the age determinations made on the second batch of samples.

(ii) Presence of excess argon and argon loss discrepancies. Pumice is a froth of volcanic glass and escaping juvenile volcanic gases. Juvenile volcanic gases may contain radiogenic argon-40 derived from the crust or upper mantle. Normally, appreciable amounts of this "excess argon" are not retained in volcanic rocks erupted on the land surface or in rocks which have cooled slowly, but very small quantities may be trapped in volcanic glasses that have been quenched rapidly. This small quantity of excess argon only becomes significant, however, in the analysis of very young volcanic glasses such as the Leakey *IB1* pumice. Because, in addition, the possible occurrence of a small argon loss discrepancy is suggested by the presence of carbonates partly replacing glass and infilling vesicles, the results of the two total degassing analyses made on the pumice (that is, 3·02 ± 1·6 m.y. (conventional K–Ar) and 3·45 ± 1·2 m.y. (total degassing ^{40}Ar/^{39}Ar)), each may contain two small inherent geological errors of opposing sign and of amounts that cannot be estimated (but are unlikely to be greater than the quoted experimental errors which are themselves large because of low potassium content and high atmospheric contamination). The possible presence of these unmeasured errors means that the best estimate of the age of the pumice which can be arrived at from the total degassing analyses would be that it lies somewhere between 2·25 and 4·62 m.y. (the total error span of the two determinations). Excess argon is not tightly held in volcanic glass; thus it is driven off at low temperatures during a ^{40}Ar/^{39}Ar age spectrum analysis. The pumice sample Leakey *IB1* was too young and potash-poor for a full age spectrum analysis, but it was possible to make a simple two-step analysis on it. All weakly held argon was driven off during a 20 min low temperature step-heating: the sample was then fused and the isotope ratios of the remaining argon measured. The apparent age obtained from this second step, 2·5 ± 0·5 m.y., can be regarded as a close minimum age for the pumice. It is most probably free of excess argon discrepancy, although not of argon loss discrepancy, and has a smaller experimental error because of the reduced atmospheric contamination.

It is unlikely that excess argon discrepancy is important in any of the crystal fraction age determinations, for this error would be insignificantly small when compared with the high potassium content of the samples. As was suggested earlier, minor variable argon loss discrepancy is likely to be present. The two total degassing analyses (that is, 2·37 ± 0·3 m.y. (conventional K–Ar) and 2·64 ± 0·29 m.y. (total degassing ^{40}Ar/^{39}Ar)) must therefore be

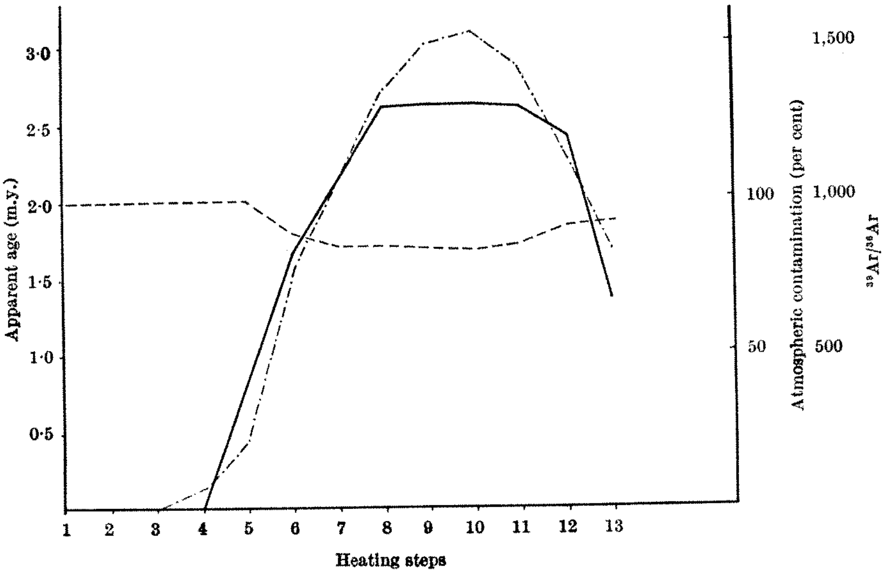

Fig. 1. ^{40}Ar/^{39}Ar age spectrum analysis of crystal fraction Leakey *IB2*. ———, Apparent age; - - -, atmospheric contamination; — · — · —, argon release.

suspect to some extent because of the possible presence of these unmeasured errors. Because the ^{40}Ar/^{39}Ar analysis was made on some of the best sanidine crystals selected from the sample provided, it is very probable that the argon loss discrepancy in this analysis is much less than in the conventional age determination which was made on the remainder of the crystal fraction.

Final resolution of the excess argon and argon loss problems was obtained from the ^{40}Ar/^{39}Ar age spectrum analysis of the best of the selected sanidine crystals (see Fig. 1). The nature of the age spectrum obtained proves that, in this sample, while excess argon discrepancy is at a minimum, a measurable amount of argon loss has occurred. The flat apparent age plateau obtained during the period of maximum argon release can be regarded, however, as a very close estimate of the true age of crystallization (that is, at 2·61 ± less than 0·26 m.y.).

Thus the age indications obtained in this survey can be summarized as follows:

Leakey *IB1* pumice: between 2·25 and 4·62 m.y.; 2·5 ± 0·5 m.y. is a close minimum age.

Leakey *IB2* crystals: 2·37 ± 0·3 m.y. is a minimum age; 2·64 ± 0·29 m.y. is a reasonably close age; and 2·61 ± less than 0·26 m.y. is a very close age estimate.

These age indications are all consistent. The best and most acceptable estimate is clearly 2·61 ± less than 0·26 m.y.

(iii) Reduction in experimental error. When the rock being dated is very young it becomes important to reduce the experimental errors to a minimum because they are frequently of a similar order of magnitude to that of the date required. The lowest errors are obtained when the potassium content of the sample is high and the atmospheric contamination is low. These conditions are best satisfied during the ^{40}Ar/^{39}Ar analyses of the selected feldspar crystals. The error on the accepted age of 2·61 m.y. is quoted as less than 0·26 m.y. because of the fourfold repetition of this apparent age and error as a plateau on the age spectrum. The overall indications of the results obtained here suggest that the real age of the tuff on the K–Ar time-scale must be very close to 2·6 m.y.

It can therefore be concluded that the best interpretation of the results of three conventional K–Ar age determinations and four ^{40}Ar/^{39}Ar age analyses on pumice, crystal and whole rock fractions of the tuff horizon in the Koobi Fora beds from east of Lake Rudolf in East Africa is that its age is very close to 2·6 m.y. (2·61 ± less than 0·26 m.y.). This is a Plio-Pleistocene age. In terms of the American succession it would seem to be equivalent to some part of the Blancan.

Early Artefacts from the Koobi Fora Area

ARTEFACTS have been recovered from only a few localities in the Koobi Fora area and no locality has provided sufficient material for the nature of the industry to be assessed in full. The fifty-one specimens described here are the largest series from one site (*KBS*). They consist of five choppers, twenty-four flakes, two refresher flakes, two roughly flaked and battered cobbles, seventeen broken flakes and chips and one unmodified cobble. Five of the flakes were *in situ* in a fine-grained silty tuff, at a depth of just under 1 m from the top of the deposit. Fourteen fragments of mammalian bones, one porcupine tooth and a bovid molar were also found at the same level. As has been noted by R. E. F. Leakey in an accompanying report, the balance of the artefacts lay on the surface, close to the *in situ* flakes and bones, distributed in such a manner as to suggest that they had originally been embedded in the tuff and had weathered out during comparatively recent times. The material of the *in situ* and surface specimens is indistinguishable, and in view of the fact that comparable artefacts do not occur outside the immediate vicinity of the site, it seems justifiable to assume provisionally that the whole series is derived from the same source. Furthermore, the few similar artefacts that are known from other sites at Koobi Fora are also associated with this tuff, although no other locality has so far been excavated or yielded *in situ* material.

A few of the surface specimens are weathered, but most are in a remarkably fresh condition and clearly have not been exposed for any length of time, either since eroding from the tuff or before being buried in it—always assuming that they are contemporaneous.

The palaeogeography of the Koobi Fora area has not yet been studied in any detail. Preliminary observations, however, indicate that the artefact-bearing tuff fills depressions, most likely former erosion channels, in the underlying sediments. At the tool site, the tuff is fine-grained and silty, but it contains coarser elements elsewhere and the fresh pumice on which the isotopic age determinations have been carried out was obtained from a locality approximately 1 mile distant. More extensive excavation will be needed before it is possible to assess the nature of the tool site, but judged on similar artefact occurrences in Bed I at Olduvai, it seems most likely to have been a temporary camping place occupied for only a brief period.

One of the *in situ* flakes and one flake from the surface were submitted to Dr R. L. Hay, Department of Geology, University of California, Berkeley, who reports on the raw materials as follows.

"Both specimens are a trachyandesite or basalt, consisting largely of plagioclase (approximately An_{50} in composition), clinopyroxene (probably augite) and glass. Plagioclase is slightly more abundant than the clinopyroxene. The specimens are strikingly similar in texture and composition and could have come from the same flow. The lava, however, is of a type rather common in the Rift Valley, and I cannot rule out the possibility of different sources."

Choppers.—These consist of two classic choppers made on cobbles in which the working edges have been boldly flaked on both faces, one somewhat weathered double-edged specimen and two smaller and less typical examples. The first two specimens are in mint condition. One is a side chopper (*KBS* 4) with alternate multidirectional flaking. No chipping or other evidence of utilization is evident. The butt is rounded and consists of cortex surface (Fig. 1*A*). The second example (*KBS* 9) is also made on a cobble and is two-edged with a working edge at either end and a third sharp edge linking the two. The edges at either end are curved and more extensively flaked on one face than the other. They are slightly chipped, apparently by use, but are still jagged and sharp and have not become blunt (Fig. 1*B*). Specimen *KBS* 34 is also double-ended, but each working edge has been flaked from one direction only. Because of weathering, it is difficult to determine whether the flaking represents deliberate shaping or is merely the result of heavy utilization. Chopper *KBS* 15 is conical and has been trimmed round the circumference of the base. This consists of a single negative scar that has served as the striking platform (Fig. 1*D*). *KBS* 24 is the smallest chopper in the series and has a mean diameter of 34 mm. The working edge is trimmed by means of a single flake on one face and three flakes on the opposite face. The tool is slightly weathered and the butt consists of cortex surface (Fig. 1*C*). The measurements for the five choppers are given in Table 1.

Flakes.—Twenty-four of the flakes are complete. They are all irregular and mostly divergent, only five examples being convergent with the maximum width at the butt. In five specimens, an area of cortex surface is visible on the dorsal aspect, indicating that these flakes were struck from cobbles or boulders. The angles of the striking platforms can be measured in twenty-one specimens and range from 90° to 120° with an average of 108°. The edges of the flakes are particularly sharp and one example shows chipping that may have been caused by use. The bulbs of percussion are variable, but on the whole are well marked. End-struck flakes predominate and amount to 63 per cent of the total. They range in size from 62 × 41 mm to 13 × 12 mm with an average length/width measurement of 44 × 33 mm. Side-struck flakes range in size from 54 × 81 mm to 18 × 23 mm, with an average of 33 × 44 mm.

Table 1. MEASUREMENTS OF THE FIVE CHOPPERS

	Length	Width	Thickness	Mean diameter	Edge length	Number of scars
KBS 4	63 mm	74 mm	57 mm	64 mm	97 mm	6
KBS 9	68	54	51	57	45 and 51	4 and 7
KBS 15	38	47	35	40	135	8
KBS 24	35	39	28	34	31	3
KBS 34	48	51	35	45	52 and 45	?

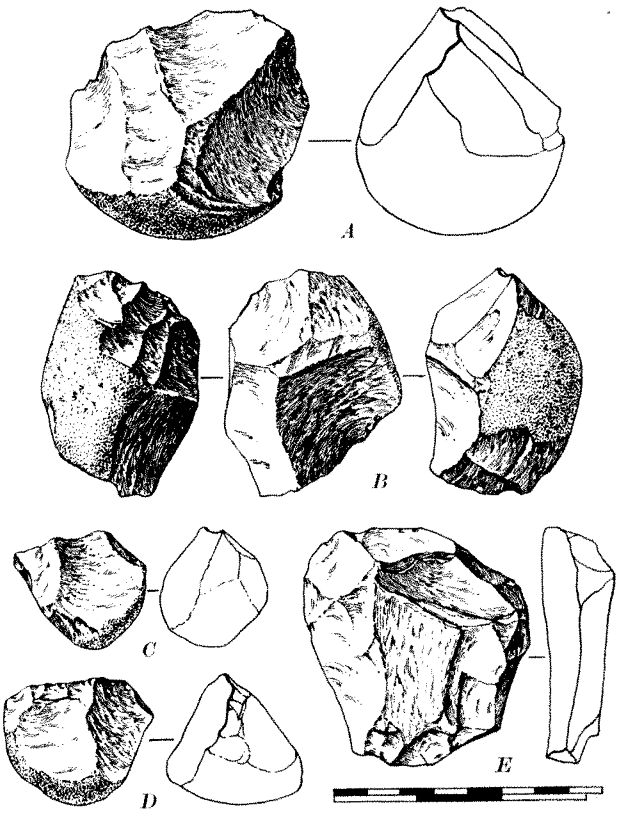

Fig. 1

Refresher Flakes.—Two flakes show the bifacially flaked crests that are characteristic of refresher flakes struck from cores and that also occur in the Oldowan on flakes that have been struck from choppers in order to re-sharpen the edges. In one specimen (Fig. 1*E*) the crest on the dorsal aspect extends along one lateral edge and then curves transversely across the width of the flake. In the second example, the crest is longitudinal and runs the whole length of the flake, from the butt to the tip. The measurements for these two flakes are 71 × 60 mm and 66 × 61 mm respectively.

Flaked and Battered Cobbles.—There are also two cobbles with indeterminate flaking and battering. One example (*KBS* 23) is considerably weathered. It has a number of negative scars and the intervening ridges are battered and crushed (86 × 64 × 53 mm). The second specimen is oblong and has crude bifacial flaking along one lateral edge as well as at one end (81 × 61 × 52 mm).

Until more *in situ* material has been obtained it is premature to comment on the elements that go to make up the artefact assemblage from Koobi Fora, or to draw parallels with the Oldowan and other early industries. It is surprising to note, however, that the technique of flaking seen on two of the choppers and on a proportion of the flakes appears to be bolder and more assured than the flaking usually seen on Oldowan tools. But it is possible that this anomaly may be due to the use of more homogeneous material in which it was possible to control with greater accuracy both the direction and the extent of fracture.

In conclusion, it can be stated that the evidence for artificially struck flakes in a tuff that has been dated at 2·6 ± 0·26 m.y. by Fitch and Miller (see their accompanying report) seems to be unquestionable. As regards the choppers and other specimens that were found on the surface, some element of doubt must remain until similar tools have been found *in situ*. But the balance of evidence indicates that these and possibly other artefacts from the Koobi Fora area are in fact derived from the tuff. If this is so, they antedate the earliest known artefacts from Bed I, Olduvai, by approximately 0·8 m.y. The few choppers found by L. S. B. Leakey at Kanam West are probably closer in age, but are not now available for comparison[1]. At Olduvai, the industry from sites immediately above the basalt that has been dated at 1·9 m.y. and that is overlain by a tuff for which an average date of 1·75 m.y. can be accepted, already contains a variety of recognizable tool types. There are several forms of choppers, polyhedrons, discoids, light and heavy duty scrapers and even a few burins. No significant evolution in the Oldowan is apparent throughout Bed I and the base of Bed II[2], a period that can be estimated to have lasted 0·4 or 0·5 m.y. The occurrence of choppers and other artefacts 0·8 m.y. before the earliest known Oldowan tools is therefore not unexpected. In fact, the multiple tool kit that was in use at Olduvai between 1·9 and 1·75 m.y. has led me to suggest that systematic tool making must have been in practice for a considerable period before that time[3].

I thank my son Richard for inviting me to describe the Koobi Fora artefacts and enabling me to visit the site where they were found, and Dr R. L. Hay for his report on the rock samples.

The sequencing of the ribosome binding sites and parts of the coat protein cistron has enabled the order of the three R17 genes to be established by direct chemical means. Translation may be influenced by the conformation of the RNA.

THE related coliphages R17, MS2, fr and f2 appear to encode only three proteins in their single-stranded RNA genome[1-4]. These are: (1) the coat protein, which is the major protein component of the virus particle (129 amino-acids[5,6]); (2) the maturation or A protein, a minor component of the virus particle (approximately 350 amino-acids[7]); and (3) the RNA replicase or synthetase, which is not present in the mature phage particle (a minimum of about 450 amino-acids[8]). The phage genome contains 3,300–3,500[9-11] nucleotide residues, of which the three cistrons account for approximately 2,800.

Conditional lethal mutants of these bacteriophages fall into three complementation groups,[1,2] which have been correlated with the three known phage proteins, but, because of the inability to obtain genetic recombination between these mutants, no genetic map of the phage has been constructed.

It is possible to detect the *in vitro* synthesis of the three phage proteins directed by the phage RNA[12-15]. This has led several groups to attempt the isolation of different forms and fragments of the RNA molecule, in order to determine their messenger activities and to infer the order of the cistrons along the RNA genome[14,16-21,25]. Their conclusions, however, are conflicting unless one admits the unlikely possibility that the closely related RNA bacteriophages have different gene orders. Moreover, all previously determined gene orders are subject to the criticism that they are based on indirect measurements and rely on various assumptions about the messenger properties *in vitro* of the RNA and its fragments.

The elucidation of the nucleotide sequences of the three ribosomal binding sites[22] and of parts of the coat protein cistron[23,24] has now made possible the determination of gene order by direct chemical means. On the basis of the distribution of these sequences between two specific fragments of the R17 RNA, we conclude that the gene order is: 5'-A protein—coat protein—synthetase-3'.

Preparation of Specific Fragments of R17 RNA

A partially purified endonuclease from *Escherichia coli* MRE600, referred to as ribonuclease IV, cleaves R17 RNA at a position about 40 per cent of the way into the molecule from the 5'-end[16,25,26]. Further cuts are introduced only slowly, permitting isolation of two specific fragments. *In vitro* translation studies in extracts from *E. coli* have shown that the 60 per cent fragment from the 3′-end directs efficient synthesis of the synthetase protein, while the 40 per cent fragment is relatively inactive as messenger[16,25]. The coat protein, which is the major product of *in vitro* protein synthesis with the native R17 RNA, is not efficiently produced by either fragment.

Investigation of the location of genes by RNA sequence methods requires ^{32}P-labelled fragments of high specific activity (about 10^6 c.p.m./μg). Because of radiation damage, RNA of such specific activity extracted from phage purified by conventional procedures is not intact, and ribonuclease IV cannot cleave it into clean fragments. By using chromatography on DEAE-cellulose for the initial step of phage purification (see legend to Fig. 1), however, damage can be minimized allowing isolation of intact RNA.

Treatment with ribonuclease IV as described[16,25,26] produces 15S and 22S fragments from the 26S native R17 RNA (Fig. 1). The 15S preparation represents the 5′ terminal 1,300–1,400 nucleotides (40 per cent) of the molecule[26]; its yield of the terminal pppGp residue[32] is nearly equivalent to that of the intact RNA (Table 1). This fragment must therefore be relatively free of material arising from other parts of the genome, as confirmed by its apparent homogeneity on polyacrylamide gels. The 22S RNA, containing 2,000–2,100 nucleotides (60 per cent)[26], comes from the 3′-end of the R17 RNA molecule; no more than 10 per cent of its chains terminate with pppGp (Table 1). On gels the 60 per cent preparation appears approximately 80 per cent homogeneous; its contaminants are smaller RNA fragments, some exhibiting the same mobility as the 40 per cent piece.

Table 1. ANALYSES OF 5′ TERMINAL pppGp

	Native RNA	60 per cent	40 per cent
Total c.p.m. ^{32}P	612,800	1,520,000	1,173,000
pppGp c.p.m.	487	302	2,180
Percentage ^{32}P in pppGp	0·079	0·020	0·186
Percentage P in pppGp (theoretical)	0·114	0·19	0·286
Percentage chains with pppGp	69	(10)	65

The pppGp analyses were carried out after alkaline hydrolysis according to Roblin[32]. The calculations are made assuming 3,500 nucleotides in the intact R17 RNA molecule. The percentage of chains with pppGp reflects the fraction of chains of that size which could have 5′ terminal pppGp.

Ribosome Binding to the Fragments

Ribosomes from *E. coli* recognize and shield from nuclease digestion the initiation regions at the beginning of the three cistrons in the R17 RNA[22]. The nucleotide sequences of these sites have been elucidated and the correspondence of each to one of the known R17 proteins has been established.

The distribution of the initiation regions between the 40 per cent and 60 per cent R17 RNA fragments was analysed using the procedure described previously for the whole RNA[22]: MRE600 ribosomes were bound to the radioactive fragments in the presence of formylated charged transfer RNA, initiation factors, and GTP at 5 mM Mg^{2+} concentration (see legend to Fig. 2). After incubation, the ends of the messenger not protected in the initiation complex were trimmed with pancreatic ribonuclease and the digested complex was isolated by sucrose gradient sedimentation. Ribosome binding sites were detected by fingerprint analysis of the radioactive RNA recovered from the 70S region of the gradient.

One set of T_1 ribonuclease fingerprints of initiation sites from the 40 per cent and 60 per cent fragments is shown in Fig. 2. Although the amount of radioactive RNA recovered was insufficient to allow accurate measurement of the relative amounts of the binding sites present in the two fragments, the visual examination of the fingerprints obtained from two sets of fragment preparations reveals that: (1) Oligonucleotides derived from the synthetase binding site (marked S in Fig. 2) are present in higher yield in the 60 per cent than in the 40 per cent fragment (the approximate ratio of 60 per cent to 40 per cent yields is of 3 or 4 : 1). (2) Oligonucleotides specific for the A protein binding site (marked A) are detected in the 40 per cent fragment only, and there at a very low level. (3) Oligonucleotides arising from the coat protein initiation region (marked C) appear primarily in the fingerprint of the binding reaction performed with the 40 per cent fragment (approximate ratio of 3 : 1 or 4 : 1, 40 : 60 per cent).

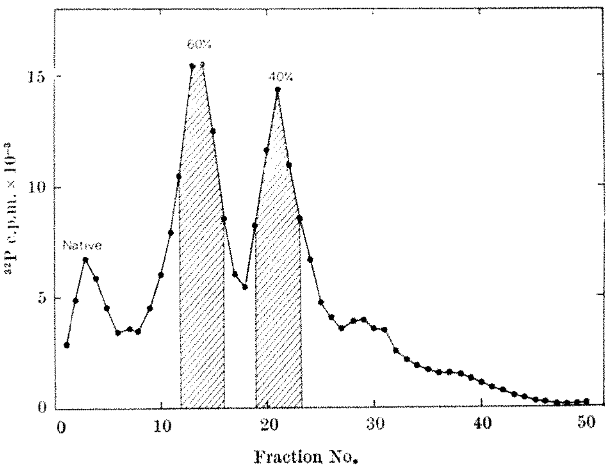

Fig. 1. Sucrose gradient preparation of fragments. ^{32}P-labelled RNA (10^6 c.p.m./μg) was digested with ribonuclease IV as described previously[25] and sedimented for 19 h in a 'Spinco SW 27' rotor at 4° C through a 5–20 per cent sucrose gradient in 0·1 M NaCl, 0·01 M sodium acetate, pH 5·0. Fractions of 0·75 ml. were collected and 1 μl. samples were counted directly in a liquid scintillation counter. Fractions 12–16 and 19–23 (cross-hatched) were pooled to give, respectively, the 60 per cent and 40 per cent preparations used in the experiments described in Figs. 3, 5 and 6 and Tables 1, 3 and 4. R17 phage was grown on ribonuclease I_{10} in low phosphate medium as described previously[9] except that half the normal amount of casamino acids was used. 20 mCi of ^{32}P-orthophosphate was added to 400 ml. of culture 12 min before phage infection. The phage were purified using a new procedure that will be described in detail elsewhere (R. F. Gesteland and P. F. Spahr, in preparation). Briefly, the phages were concentrated by passage of the clarified lysate through a 20 ml. bed volume column of DEAE-cellulose. After washing the column with SSC (0·15 M NaCl, 0·015 M Na citrate, pH 7·0), the phages were eluted with 4 × SSC and banded to equilibrium in CsCl. The phages were freed of small RNA fragments and CsCl by filtration through 'Sephadex G-150'. The RNA extracted from R17 purified in this manner was intact as demonstrated by sedimentation analysis after formaldehyde treatment.

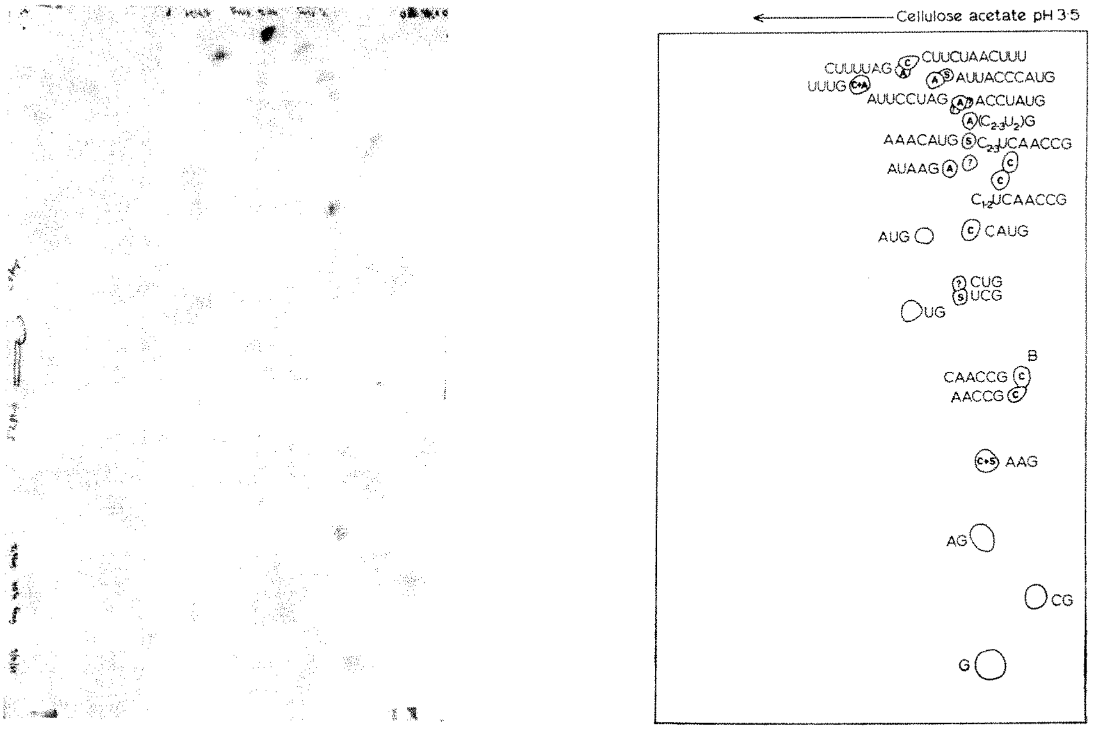
Allocation of T_1 Oligonucleotides to the Fragments

If ^{32}P-labelled R17 RNA is exhaustively digested with T_1 ribonuclease, it is possible to fractionate many of the larger oligonucleotides by a two dimensional fingerprinting system using ionophoresis followed by homochromatography on thin layers of DEAE-cellulose[28]. The characterization of one such T_1 oligonucleotide coding for amino-acids 57 to 61 of the R17 coat protein[5,6] has been described[23].

To isolate further large T_1 oligonucleotides whose sequences could be related to known positions in the R17 RNA molecule, it was necessary to obtain greater resolution in the homochromatography system. This was achieved by partially degrading the RNA of the homomixture, and chromatographing on longer thin layer plates of DEAE-cellulose, as described in the legend to Fig. 3. An autoradiograph of the separation obtained for the T_1 digestion products of the whole R17 RNA molecule is shown in Fig. 3*a*. In addition to the large oligonucleotides many smaller products are resolved if their mobility in the first dimension is particularly high or low.

When the sequences of the well separated spots from such a homochromatogram were investigated, certain of them were found to come from recognizable regions of the R17 genome. Eight of these T_1 oligonucleotides are indicated in Fig. 3*a* and their sequences and origins

T$_1$ RNase fingerprint of initiation sites from 40 per cent fragment



T$_1$ RNase fingerprint of initiation sites from 60 per cent fragment

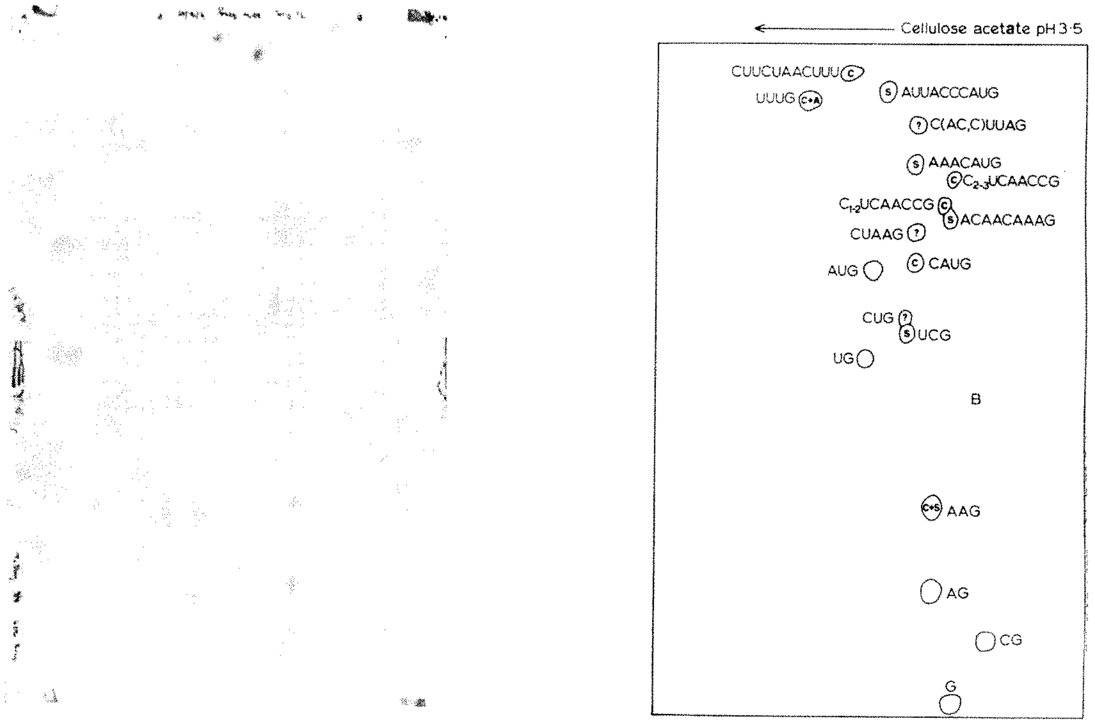


Fig. 2. T$_1$ ribonuclease fingerprints of ribosomal binding sites from the 40 per cent and 60 per cent fragments. Parallel binding reactions were performed at 37° C in 30 μl. of solution containing: 0·1 M Tris chloride (pH 7·4), 0·05 M NH_4Cl, 0·005 M magnesium acetate, 4·0 $A_{260\ nm}$ units of MRE600 ribosomes, 60 μg crude initiation factors, 0·0002 M GTP, 2·8 $A_{260\ nm}$ units of formylated charged mixed tRNA, and either 16 μg ($1·1 \times 10^7$ c.p.m.) of the 60 per cent fragment or 11 μg ($7·7 \times 10^6$ c.p.m.) of the 40 per cent fragment (incubated in 5 μl. of 0·001 M EDTA for 7 min at 37° C before addition). Ribosomes, initiation factors and fMet-tRNA were prepared as described previously[22]. After 12 min of incubation, the binding reaction mixtures were cooled; 0·15 μg of pancreatic ribonuclease was added and incubation at 22° C was continued for 15 min. Following sucrose gradient fractionation[22] the 70S regions were pooled and extracted with phenol in the presence of 0·1 per cent sodium dodecyl sulphate. The resulting 150 μg of RNA was digested with 7 μg of T$_1$ ribonuclease and fingerprinted as described elsewhere[22]. The identity of each oligonucleotide was checked by analysis of its pancreatic ribonuclease digestion products. With the exception of a few spots of unknown origin, each oligonucleotide in the fingerprints is seen to derive from one or another of the three established ribosome binding regions (Fig. 7) as indicated: A = A protein, C = coat protein, S = synthetase. Several oligonucleotides marked A do not appear in the established sequences (Fig. 7); they seem to originate from more extended ribosome-bound fragments and have been identified as linked to the A protein initiation site.

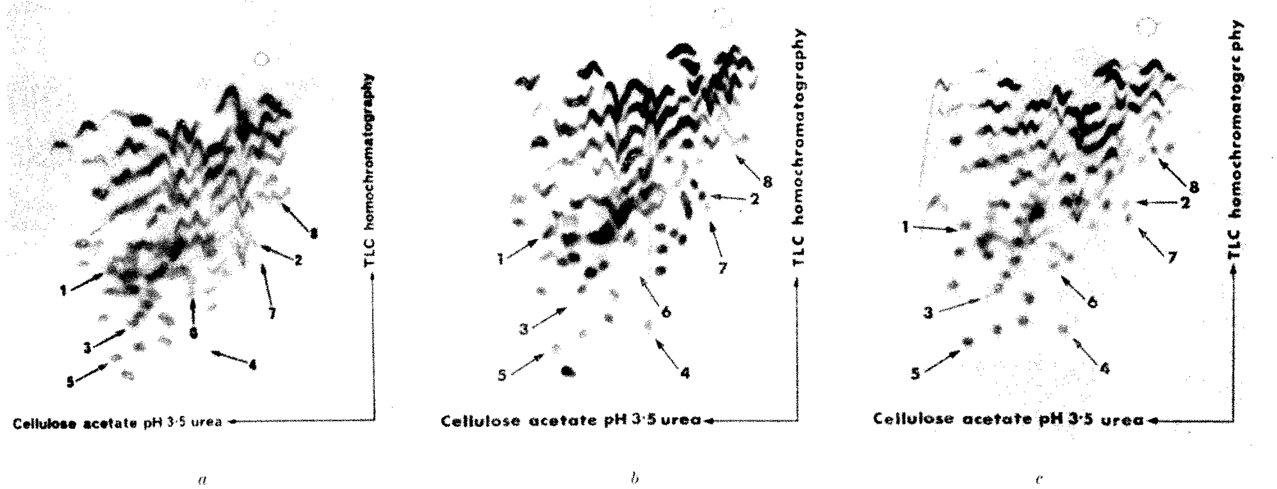

a *b* *c*

Fig. 3. Two-dimensional thin layer homochromatography fingerprints of T_1 digests of intact R17 RNA (*a*), the 40 per cent fragment (*b*) and the 60 per cent fragment (*c*). For the intact molecule, 20 μg of ^{32}P-RNA (about 10^7 c.p.m.) was digested with 1 μg of ribonuclease T_1 in 3–4 μl. of 0·01 M Tris-HCl, *p*H 7·4, containing 0·001 M EDTA, at 37° C for 30 min. The products were fractionated by ionophoresis on cellulose acetate in 7 M urea, *p*H 3·5, as a first dimension, followed by homochromatography[28], using homomixture *c* with DEAE-cellulose and cellulose in the ratio 1 : 7·5 on a 20 cm × 40 cm plate. For the fragments about 10^6 c.p.m. of each was made up to 20 μg with non-radioactive carrier tRNA: T_1 digestion and fractionation of products were performed as above. The numbered spots are identified in Table 2.

listed in Table 2. Sequence *1* is obtained by J. M. Adams and S. Cory (personal communication) in an R17 RNA fragment of approximately 75 nucleotides containing pppGp, the 5′ terminus of the RNA molecule. As shown in Fig. 4, sequences *3*, *4* and *5* are related to amino-acid sequences in the coat protein[5,6] *3* being an extension of the coat protein ribosome binding site[22] (Fig. 7). (Sequence *3* is the same as that proposed by Robinson, Frist and Kaesberg[29] from work with a strain of R17 having an amber mutation at position 6 of the coat protein.) Sequence *6* is homologous with the beginning of the synthetase binding site[22] (Fig. 7) and is found in an RNA fragment containing, and extending beyond, the 3′-terminus of the coat protein cistron[24]. Sequence *8* is the 3′-end of the R17 RNA molecule[30]. Owing to their size and composition, it was not possible to locate any of the A protein binding site T_1 oligonucleotides as pure spots on this homochromatographic system.

Figs. 3*b* and 3*c* are fingerprints of the 40 per cent and 60 per cent fragments, analogous to that of the whole molecule (Fig. 3*a*). With the exception of oligonucleotide *3* which appears in low yield in both fragments (the significance of which will be discussed later), each of the well resolved oligonucleotides occurs in major yield in one or other of the fragment preparations, but not in both. This finding supports the idea of a single primary site of cleavage by ribonuclease IV in the R17 RNA molecule, giving rise to the two fragments. The presence of sequence *1* as a major spot in the 40 per cent fingerprint, and similarly of sequence *8* in the 60 per cent fingerprint, confirms the fragment orientation in the original RNA molecule based on pppGp analyses[16,25,26].

Table 2. SEQUENCES AND LOCATION OF SPECIFIC T_1 OLIGONUCLEOTIDES

Oligonucleotide (see Fig. 3)	Sequence	Location
1	CCAUUUUUAAUG	Approximately 50 residues from the 5′-end
2	(C)CCUCAACCG*	Coat protein ribosome binding site, proximal to initiating AUG
3	CUUCUAACUUUACUCAG	Coat protein cistron (amino-acids 1–6)
4	CAAAUACACCAUUAAAG	Coat protein cistron (amino-acids 57–61)
5	AAUUAACUAUUCCAAUUUUCG	Coat protein cistron (amino-acids 89–95)
6	CCAUUCAAACAUG	Synthetase ribosome binding site
7	ACAACAAAG	Synthetase ribosome binding site
8	$\text{UUACCACCCA}_{\text{OH}}$	3′-end

* It is not clear whether this oligonucleotide has two or three C residues at the 5′-end, although the best data at present suggest there are three.

The methods used to verify each of the above sequences will be published elsewhere (P. G. N. J., unpublished results).

Fig. 4. Sequences of T_1 oligonucleotides *3*, *4* and *5*, showing their relationship to amino-acid sequences in the R17 coat protein[5,6].

A quantitative measure of the yields of oligonucleotides *1*–*8* in the 40 per cent and 60 per cent fragments was obtained by scraping the appropriate spots off the two fingerprints and counting them directly (Table 3, columns (*a*) and (*c*). The identity of each was then checked by analysis of its pancreatic ribonuclease digestion products. Sequences *1* and *8* can conveniently be used as standards with which to compare the yields of the other oligonucleotides as tabulated in columns (*e*) and (*f*) of Table 3. Sequence *2* is present in the 40 per cent fragment in 87 per cent yield whereas *3* to *8* appear in 25 per cent yield or less. Conversely, the 60 per cent fragment contains oligonucleotides *4* to *7* in better than 80 per cent yield and *1* to *3* in less than 23 per cent yield. The relative recovery of some oligonucleotides may be low, for the efficiency of transfer from the first dimension to the DEAE-cellulose thin layer[28] may vary both along the length of the cellulose acetate strip and with the size and/or composition of the oligonucleotide. Nevertheless,

Table 3. YIELDS OF SPECIFIC T_1 OLIGONUCLEOTIDES FROM THE 40 PER CENT AND 60 PER CENT FRAGMENTS

Oligonucleotide (No. of phosphates)	(*a*) 40 per cent C.p.m. (total)	(*b*) 40 per cent C.p.m. per phosphate	(*c*) 60 per cent C.p.m. (total)	(*d*) 60 per cent C.p.m. per phosphate	(*e*) Percentage yield (see text) 40 per cent relative to *1*	(*f*) Percentage yield (see text) 60 per cent relative to *8*
1 (12)	575	47·9	76	6·3	—	23

6 (13)	130	10·0	286	22·0	21	80
7 (9)	107	11·9	249	27·7	25	100
8 (9)	78	8·7	249	27·7	18	—

* See footnote to Table 2.

Glass sinters were counted before and after taking up the DEAE-cellulose corresponding to the marker T_1 oligonucleotides in a 'Unilux I' (Nuclear Chicago) scintillation counter, without the addition of scintillator (setting C50). The differences between these two readings are tabulated in columns (*a*) and (*c*).

After its radioactivity had been counted, each oligonucleotide was eluted and its identity checked by analysis of its pancreatic ribonuclease digestion products. The radioactivity from spots observed in minor yield was shown to come from the oligonucleotides in question rather than from contaminants.

the data allow unequivocal assignment of oligonucleotides *2* to *7* (with the exception of *3*) either to the 40 per cent or to the 60 per cent fragment. The level of contamination of each fragment by the other is consistent with the pppGp analyses and the results of ribosome binding.

Table 4. RELATIVE YIELDS OF A PROTEIN INITIATION SITE OLIGONUCLEOTIDES FROM COMPLEXES FORMED BETWEEN *B. stearothermophilus* RIBOSOMES AND THE 40 PER CENT AND 60 PER CENT FRAGMENTS

Oligonucleotide	Counts per min 40 per cent	Counts per min 60 per cent	Relative yield 40 per cent : 60 per cent
UUUG	6,450	1,200	5·4
CUUUUAG	7,350	1,500	4·9
ACCUAUG	10,400	1,850	5·6

Oligonucleotide spots were cut from the fingerprints shown in Fig. 6 and counted in a toluene scintillator. The actual counts per min obtained for the 60 per cent oligonucleotides have been multiplied by a factor of 1·75 to adjust for the fact that non-equimolar amounts of the two fragments were used in the initial binding reactions. The 40 per cent : 60 per cent ratio for CUUUUAG is probably least accurate because this oligonucleotide appears near the 3′-end of the A protein ribosomal binding site (see Fig. 7) and therefore often experiences internal cleavage upon pancreatic ribonuclease digestion of the initiation complex.

Location of A Protein Initiation Site

Because no unique T_1 oligonucleotide from the A protein initiation site could be identified in the homochromatogram of a complete T_1 ribonuclease digest of R17 RNA, an alternative method was used to estimate the amounts of A protein initiation site in the 40 per cent and 60 per cent fragments. When ribosomes from *Bacillus stearothermophilus*, rather than from *E. coli*, are used for the *in vitro* translation of f2 RNA, only the A protein is initiated and synthesized[31]. Similarly with R17 RNA[22], the A protein initiation site alone binds to *B. stearothermophilus* ribosomes; no recognition of the coat protein or synthetase sites can be detected. Moreover, at 65° C, *B. stearothermophilus* ribosomes attach to the beginning of the A protein cistron with extremely high efficiency. At least 50 per cent of the theoretical number of A sites can be recovered from *B. stearothermophilus* ribosomes as compared with approximately 3 per cent from *E. coli* ribosomes (J. A. S., unpublished observation).

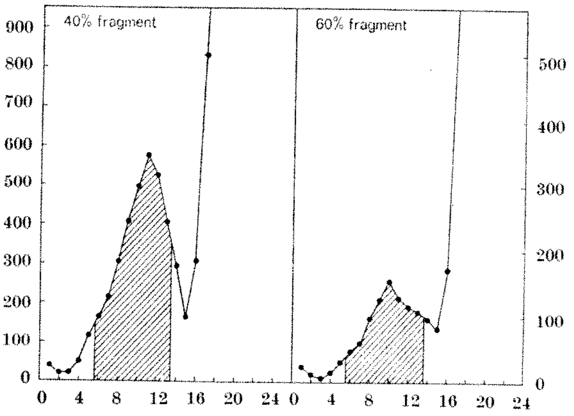

Fig. 5. Initiation complexes formed between ribosomes from *B. stearothermophilus* and the 40 per cent and 60 per cent fragments. Parallel binding reactions were performed at 66° C in 40 μl. of solution containing: 0·1 M NH_4 cacodylate (*p*H 7·1), 0·1 M NH_4Cl, 0·008 M magnesium acetate, 0·0002 M GTP, 4·5 $A_{260\text{ nm}}$ units of *B. stearothermophilus* ribosomes (prepared as described previously[22]), 4·0 $A_{260\text{ nm}}$ units of formylated charged mixed tRNA, and either 42 μg ($1·4 \times 10^7$ c.p.m.) of the 40 per cent fragment or 36 μg ($1·2 \times 10^7$ c.p.m.) of the 60 per cent fragment. After 8 min of incubation, the binding reaction mixtures were cooled; 0·2 μg of pancreatic ribonuclease was added and incubation continued for 15 min at 22° C. Sucrose gradient centrifugation was performed as described previously[22] and 1/40 volume aliquots of the fractions were counted. In the diagram the ^{32}P c.p.m. scales have been adjusted because non-equimolar amounts of the two fragments were used in the binding reactions. The fraction of A protein sites bound was calculated assuming that the average length of an initiator fragment is 30 nucleotides. Because 1 per cent of the radioactivity initially present in the 40 per cent fragment binding reaction and 0·3 per cent of that in the 60 per cent reaction appear in the 70S region of the gradients, a total of about 60 per cent of the theoretical number of A sites was recovered.

Portions of the same 40 per cent and 60 per cent fragment preparations used for pppGp analyses and homochromatography (Fig. 3 and Tables 1 and 3) were incubated with *B. stearothermophilus* ribosomes, treated with nuclease and sedimented through sucrose gradients as shown in Fig. 5. It is clear that significantly more radioactive RNA is protected when the initiation complex is made with the 40 per cent fragment than with the 60 per cent fragment. Furthermore, fingerprint analyses (Fig. 6) of the material indicated as cross-hatched in Fig. 5 demonstrate that virtually all the ribosome bound radioactive RNA from the 40 per cent fragment derives from the A protein initiation site (see Fig. 7). The material from the 60 per cent fragment gives a less clean fingerprint, containing a higher background of non-specific oligonucleotides. The three large T_1 oligonucleotides arising from the interior of the A protein binding site were cut from the two fingerprints and counted directly (Table 4). In this experiment, in which approximately 60 per cent of the theoretical number of A sites were recovered, a five-fold higher yield of the A protein initiation region from the 40 per cent than from the 60 per cent fragment is observed.

Biochemical Map for R17 RNA

From the data given in Tables 3 and 4, it is possible to construct the biochemical map of the R17 genome illustrated in Fig. 7. The crucial assignment of the coat protein gene to the middle cistron is unambiguous, for T_1 oligonucleotide *2*, which arises from the 5′ end of the coat protein ribosomal binding site, is found in good yield in the 40 per cent fragment, whereas oligonucleotides *4* and *5*, from the interior of the coat protein gene, are recovered primarily from the 60 per cent fragment. Thus ribonuclease IV most often cleaves the R17 RNA somewhere between the beginning of the coat gene and the nucleotides coding for amino-acids 57 to 61 of this protein. The low yield of oligonucleotide *3* from both the 40 per cent and the 60 per cent fragment preparations further pinpoints the principal site of ribonuclease IV attack to the region coding for the first six amino-acids of the coat protein and locates this oligonucleotide at a position about 40 per cent of the way along the R17 RNA molecule.

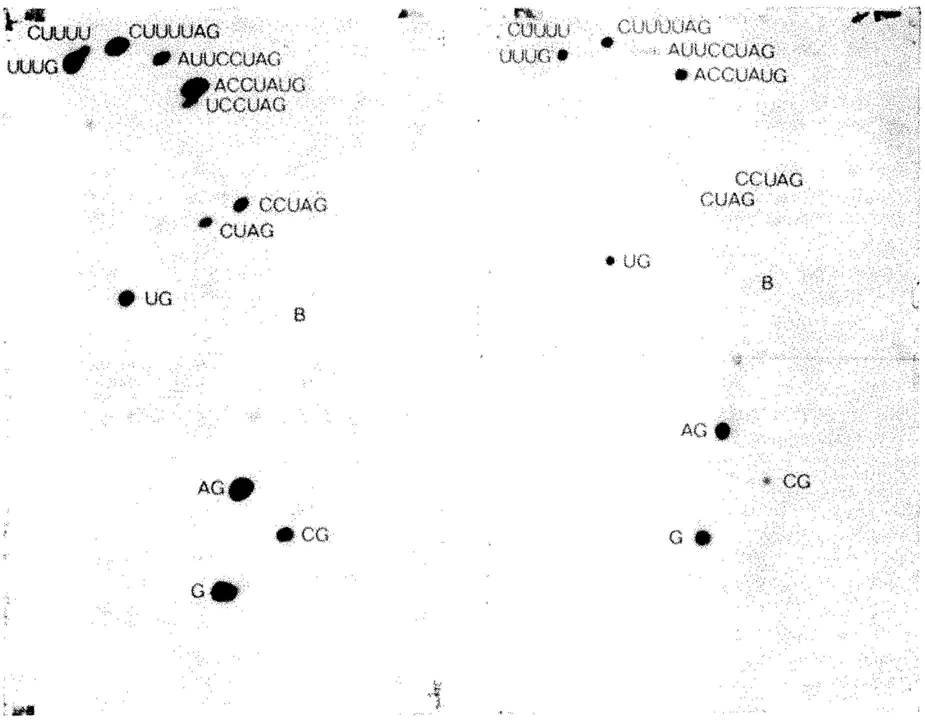

Fig. 6. T_1 ribonuclease fingerprints of initiation complexes formed between *B. stearothermophilus* ribosomes and the 40 per cent and 60 per cent fragments. Left: 40 per cent; right: 60 per cent. Fractions 6–13 from the sucrose gradients illustrated in Fig. 5 were pooled and extracted with phenol in the presence of 0·1 per cent sodium dodecyl sulphate. T_1 ribonuclease digestion and fingerprint analyses of the resulting RNA were performed as described previously[22]. Because non-equimolar amounts of the two fragments were used in the initial binding reactions, the 40 per cent fingerprint was exposed for 30 h, and the 60 per cent for 52 h to allow direct comparison.

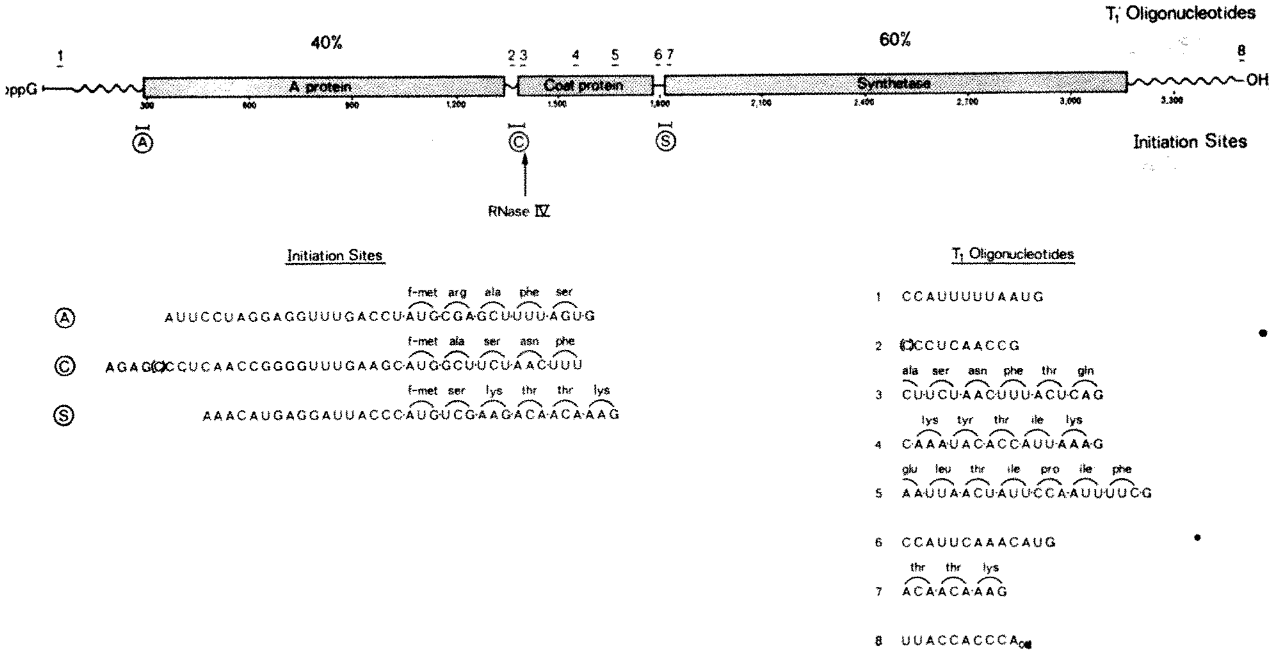

Fig. 7. Biochemical map of the R17 RNA (drawn to scale). An RNA chain length of 3,500 nucleotides has been assumed and the best molecular weight estimates for the A protein and synthetase were used. The eight specific T_1 oligonucleotides and the ribosomal binding sites have been located as accurately as possible along the genome. Wavy lines indicate that the actual lengths of the corresponding regions are unknown.

Once the position of the coat protein cistron has been assigned, it follows that each of the remaining genes must be wholly contained in one or the other of the two R17 RNA fragments. The high yields in the 60 per cent fragment of oligonucleotides *6* and *7*, which arise from the initiation region of the synthetase cistron, place this gene at the 3′ end of the RNA; and the results of the binding experiments performed with *B. stearothermophilus* ribosomes strongly support the location of the A cistron nearest the 5′ terminus.

The recent elucidation of the nucleotide sequence of the entire intercistronic region between the end of the coat protein and the beginning of the synthetase genes[22,24] eliminates any doubt that the synthetase cistron directly follows the coat protein cistron in the R17 genome. Our knowledge of the sequence also allows us to draw this region to scale (36 nucleotides) in the biochemical map. The size of the intercistronic region between the A protein and the coat protein cistrons has been assumed to be the same.

The untranslated regions at the two ends of the R17 genome are the major uncertainties remaining in the map. The first 75 nucleotides (and probably the first 100 nucleotides) do not overlap the A protein initiation site (J. M. Adams and S. Cory, personal communication) and at least 11 nucleotides at the 3′ end of the RNA are not included in the synthetase cistron[30]. But because the RNA has been variously estimated to contain 3,300[9,10] to 3,500[11] nucleotides and the molecular weights of the A and synthetase proteins have not been precisely determined, both the total lengths and the manner of distribution of the remaining untranslated material between the termini of the R17 RNA molecule are unknown.

Ribonuclease Cleavage and RNA Conformation

Identification of the principal site of ribonuclease IV attack in the R17 RNA molecule clarifies many results previously obtained in studies of the 40 per cent and 60 per cent fragments[16,25]. Although the complete coat protein ribosomal binding site is usually retained by the 40 per cent fragment (preliminary results of J. M. Adams and S. Cory (personal communication) suggest that ribonuclease IV cleavage may occur specifically after the phenylalanine codon UUU), any polypeptides produced would be too short to be detected in the conventional assay systems. This, in addition to the low level of A protein synthesis in extracts from *E. coli*[14,15], explains the relative inactivity of the 40 per cent fragment as a messenger *in vitro*[16,25]. The 60 per cent fragment, on the other hand, efficiently directs synthetase production; the amount of coat protein it initiates (20 per cent to 25 per cent that of the intact RNA[16,25]) might suggest a second site of attack by ribonuclease N (ref. 25), but the degree of purity of the fragment preparations examined here is not sufficient to reveal more than the one major site of attack.

The fact that ribonuclease IV cleaves in the vicinity of the coat protein initiator strengthens previous suggestions that this area lies in an exposed region of the intact R17 RNA molecule[25]. Because several nucleases in addition to ribonuclease IV yield fragments of about 22S and 15S as the first cleavage products (refs. 33–35 and personal communication of H. Boedtker and H. D. Robertson), it seems that isolated bacteriophage RNAs may possess not only ordered regions of secondary structure[22–24,27] but also a well defined tertiary structure. The beginning of the coat gene may be most readily accessible not only to nuclease attack but also to ribosome attachment, possibly contributing to the high relative frequency of initiation of coat protein synthesis.

Translation and Gene Order

The genome of the RNA bacteriophages, either *in vivo* or *in vitro*, directs the synthesis of very different amounts of the three proteins. For example, the molar amount of coat protein made can exceed that of synthetase and A protein by three and twenty-fold respectively[14]. Translation is also subject to a polar effect whereby an amber mutation at position 6 of the coat protein drastically lowers the production of synthetase[36–39,42]. Because both these phenomena are demonstrable *in vitro*, they must reflect intrinsic properties of the phage RNA molecule, and any explanation of them must be consistent with the gene order.

Polarity and the high relative rate of coat protein synthesis have suggested that the RNA bacteriophage genome is read sequentially[38,40], starting with the coat cistron. The gene order established here, however, proves that translation of the R17 RNA cannot be wholly sequential. Moreover, because the A protein (which is made in smallest amount), is encoded before the coat protein, independent entry of ribosomes at the beginning of the coat gene is obligatory. The actual levels of synthesis of the three proteins very likely reflect different rates of initiation, which in turn may be influenced not only by the nucleotide sequences of the initiation regions but also by the secondary and tertiary structure of the RNA molecule.

Because ribosomes have independent access to initiation sites on fragmented RNA[14,22,41], polarity also cannot depend on sequential reading of the phage genome. In other words, the fact that the synthetase gene follows the coat cistron may be irrelevant; polarity could arise from defined secondary or tertiary structure in the intact phage RNA molecule[14,22,25,36,37,39]. The initially inaccessible synthetase binding site could be made accessible by changes in the folding of the RNA brought about either by the ribosome as it translates the coat cistron or by the removal of large segments of the molecule through nuclease action (suggested by the fact that position 6 amber mutants in the 60 per cent fragment seem to have lost their polarity[25]).

In conclusion we stress that the RNA bacteriophage genome may not be the typical operon that is so frequently assumed. The messenger activity appears to be subject to strict secondary and tertiary structure constraints, imposed possibly because it must fold efficiently into a spherical virus particle. Whether similar mechanisms operate in bacterial and other messengers is not known.

We thank Dr F. Sanger for his interest and encouragement, M. S. Bretscher for help in preparing the manuscript, R. Crouch and B. G. Barrell for helpful discussions, and Mrs J. Michelbank for technical assistance. This research was supported by a Medical Research Council scholarship (to P. G. N. J.), postdoctoral fellowships from the US National Science Foundation and the Jane Coffin Childs Memorial Fund for Medical Research (to J. A. S.), a grant from the US National Science Foundation and a Public Health Service career development award (to R. F. G.), and the Fonds National Suisse de la Recherche Scientifique (to P. F. S.).

Trypsinogen molecules from two species of different evolutionary periods are compared. Homology has been established by the sequencing of over half the amino-acids of the dogfish enzyme.

THE concept of homology in primary structure has now been amply documented in a variety of protein and enzyme systems[1,2]. In particular, it has been shown that a significant degree of homology exists within the class of mammalian serine proteases, including trypsin, chymotrypsins A and B, elastase and thrombin[3]. Recent investigations have extended these results to show that the three-dimensional structure also reflects these similarities[4]. It may be tentatively concluded that enzymes with homologous amino-acid sequences possess similar three-dimensional structures as well. In order to extend the analysis for homology to species of earlier evolutionary periods, we have examined the chemical structure of trypsinogen isolated from the pancreas of the spiny Pacific dogfish with the view of making a detailed comparison with the analogous bovine zymogen. A preliminary examination of the primary structure has now been completed and certain points of similarity can already be discerned.

Dogfish trypsinogen was isolated from freshly excised pancreas glands of dogfish caught in and around the waters of Puget Sound. After extraction and chromatography, the crude trypsinogen fraction was adjusted to *p*H 3, treated with ammonium sulphate, and finally purified on 'SE-Sephadex' (personal communication from R. Haynes, W. P. W. and R. W. T.).

Amino-acid Composition and Structure

The amino-acid composition of dogfish trypsinogen was determined from acid hydrolysates as listed in Table 1 and compared with the composition of the bovine zymogen. Differences in several amino-acids, such as serine, methionine, arginine, histidine and lysine, are evident. Yet, when compared with five other trypsinogens or trypsins, including bovine, porcine[8], ovine[9], human[10] and starfish (H. N. and W. P. W., manuscript in preparation), only the methionine and histidine contents of the dogfish protein seem at variance to the averages, though the serine and threonine total is somewhat lower than the others[11].

The determination of the amino-acid sequence was initiated by isolation of the tryptic peptides from trypsinogen reduced and alkylated with ethylenimine. All of the tryptic peptides were soluble. Digests of S-(β-aminoethyl)-trypsinogen and native trypsinogen with pepsin were also prepared. Tryptic and peptic digests of S-(β-aminoethyl)-trypsinogen were separated on 'Dowex 50 × 8' with double linear gradients of pyridine acetate[12]. The fractions were tested for purity by electrophoresis and subfractionated on either 'Dowex 1 × 2' or 'Dowex 50 × 2'[14]. Purified peptides were sequenced by Edman degradation and by

carboxypeptidase A and B hydrolysis[13]. The peptic peptides from native trypsinogen were purified on columns of 'SE-Sephadex' (R. A. B. and K. A. W., submitted for publication) and subfractionated on columns of Dowex as before. Of the three digests, only the tryptic peptides were extensively examined.

The composite structure, deduced from the peptides isolated from these three digests, is shown in Fig. 1. In view of the preliminary nature of the data, it is not surprising that many of the requisite overlaps needed to produce a rigorous structure are missing, although it was readily apparent early in these studies that a high degree of homology to the bovine protein did exist and that the known structure of the bovine protein could therefore serve as a tentative guide for aligning the various peptides isolated from the dogfish zymogen. Thus the structure presented in Fig. 1 relies heavily on the bovine structure as a template, and any conclusions regarding their homologous relation must be viewed within that limitation at the present time.

Comparison with the Bovine Enzyme

As shown in Fig. 1, 205 of the 229 amino-acids comprising the bovine protein are accounted for by peptides isolated from one or more of the three digests of the dogfish protein. Of these 205, 123 have been positioned by sequence analysis and can be compared with the bovine enzyme. Eighty-five (69 per cent) were found to possess the same amino-acid residue in both proteins. Thus even in the absence of the complete sequence, the similarity of these two proteins is sufficient to be certain of their homology.

The functional residues that have been identified from chemical modification experiments[14,15] and by deduction from X-ray data of the structurally homologous enzyme α-chymotrypsin[16] can all be located in the portions of the molecule presented. Histidine 46, serine 183, and possibly aspartic acid 90 (ref. 3)—all catalytically significant residues—and aspartic acid 177, which has been implicated as the binding site of the positive charge associated with the side chain of the tryptic substrates[17], have been placed directly or by compositional data. In addition, the sequences surrounding these residues are almost identical.

The analysis also revealed evidence for amino-acid replacement sites. In one case, two peptides of closely similar composition and structure apparently correspond to residues 169–176. Whereas the bovine protein possesses alanine, tyrosine and leucine at positions 169, 171 and 172, one peptide of the dogfish protein contains valine, tyrosine and methionine, while the other contains alanine, phenylalanine and leucine, respectively, on the basis of the best fit of the composition. In the second case, the

Fig. 1. Comparison of the amino-acid sequence of bovine trypsinogen[7] with the partial sequence of dogfish trypsinogen. Peptides positioned by analogy to the bovine protein are indicated by brackets. Unknown sequences are indicated by parentheses. Except at position 137, blank areas indicate lack of peptides to complete these positions at present.

carboxyl terminal residue of the protein is occupied by either alanine or valine.

Several other points of interest deserve comment. First, the amino terminal portion of the molecule, which has been partly sequenced, indicates that dogfish trypsinogen probably contains an activation peptide with the sequence H-Ala–Pro–Asx–Asx–Asx–Asx–Lys. The position of the sixth and seventh residues has not been confirmed nor has the nature of the side chain groups of the four aspartic acid/asparagine residues. By analogy with other trypsinogens[9], these are likely to be aspartic acid. It is of interest to note that tryptic digestion of S-(β-aminoethyl)-trypsinogen did not cleave the lysyl–isoleucine bond associated with activation of the native zymogen, an observation in accord with that of Pèchere *et al.*[18] with bovine S-sulphotrypsinogen.

Second, the tyrosyl residue at position 137 of the bovine protein has apparently been deleted in the dogfish protein because four different peptides from both the tryptic and peptic digestions have been assigned to this region. Because dogfish trypsinogen has an additional residue at the N-terminus, the two proteins are of similar if not identical length.

Although the cystinyl peptides have not yet been fully characterized, it is likely that the positions of the disulphide bonds in the dogfish protein are identical to those in the bovine protein. In fact, the ten residues of half-cystine already located occur at identical positions in both proteins. Only two residues of half-cystine, at positions 203 and 216, have not been isolated, but because these two residues are bonded in the bovine protein to the half-cystinyl residues at positions 179 and 115, respectively, and are present in identical positions in the dogfish protein, it may be supposed that the missing half-cystinyl residues occupy identical, or very nearly identical, positions in the dogfish protein. The probable identity of the disulphide bridges as well as the high degree of homology already documented suggest that the three-dimensional structures of these two proteins will be very similar.

Plate Tectonics of the Mediterranean Region

by

D. P. McKENZIE

Department of Geodesy and Geophysics,
University of Cambridge,
Madingley Rise, Cambridge

The seismicity and fault plane solutions in the Mediterranean area show that two small rapidly moving plates exist in the Eastern Mediterranean, and such plates may be a common feature of contracting ocean basins. The results show that the concepts of plate tectonics apply to instantaneous motions across continental plate boundaries.

THE hypothesis of sea floor spreading[1-5] has been extended recently to include all motions observed at the Earth's surface. The additional hypothesis required is that all aseismic areas of the surface move as rigid plates without internal deformation. The new theory is often called "plate tectonics", to distinguish it from earlier and less precise versions of the theory of continental drift. Plate tectonics was first suggested by Wilson[6] and by Bullard *et al.*[7], but has been applied only recently to the tectonics of ridges and trenches[8-11]. It is clear from this recent work that the assumption of plate rigidity is justified, and that plate tectonics provides an excellent description of present motions. In its original form the theory had, however, several limitations. Perhaps the most important was that the evolution of plates was not considered at all; the theory was essentially an instantaneous theory only. This limitation has now been partly overcome[12]. Another major shortcoming was that the simple concepts of plate tectonics could not be applied to continental boundaries. The reason for this difficulty is the complicated nature of most plate boundaries wherever they cross continents. In such regions no sharp seismic boundary exists, and the focal mechanisms of earthquakes do not reflect the motion of the major plates on each side in any simple way (Fig. 1). This behaviour is in striking contrast to the properties of plate boundaries in oceanic areas[11], where the majority of earthquake mechanisms are directly related to the plate movements and the width of the seismic zones is often less than the present errors in epicentre locations. This difference between the tectonics of oceans and continents is not caused by the use of different methods on land and at sea, for the same worldwide distribution of seismic stations is used for all seismic studies.

The relation between sea floor spreading and continental geology has always been of interest, but no progress can be made until the nature of continental plate boundaries has been understood. For several reasons the Mediterranean region seemed to be a suitable area for this purpose. The entire region is seismically active, and many of the surrounding countries maintain good seismic stations. Also the outlines of the land and the marine geology of the area are known. Perhaps the most important reason was the general belief among land geologists that a large ocean, Tethys, once existed between Eurasia and Africa during the Cretaceous and early Tertiary time. The present Mediterranean is believed to be the remnant of this ocean. There was therefore some hope that the present tectonics of the area would demonstrate what happens when a trench attempts to consume a continent.

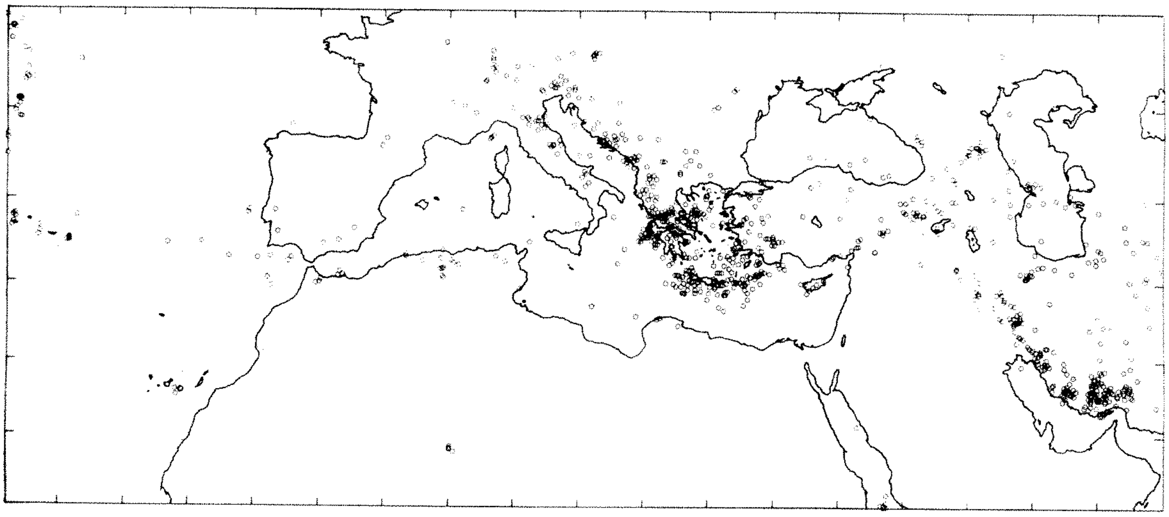

Fig. 1. Epicentres of all earthquakes with foci shallower than 70 km located by the Coast and Geodetic Survey between 1962 and 1967. The scattered activity in Eastern Turkey and Persia shows that the northward movement of Arabia is not taken up on a single fault. Six years' observations are not sufficient to show the North Anatolian Fault, though the Aegean plate is well defined. The plate boundary across North Africa is much less active than those further east, and continues into the Atlantic as the Azores–Gibraltar Ridge.

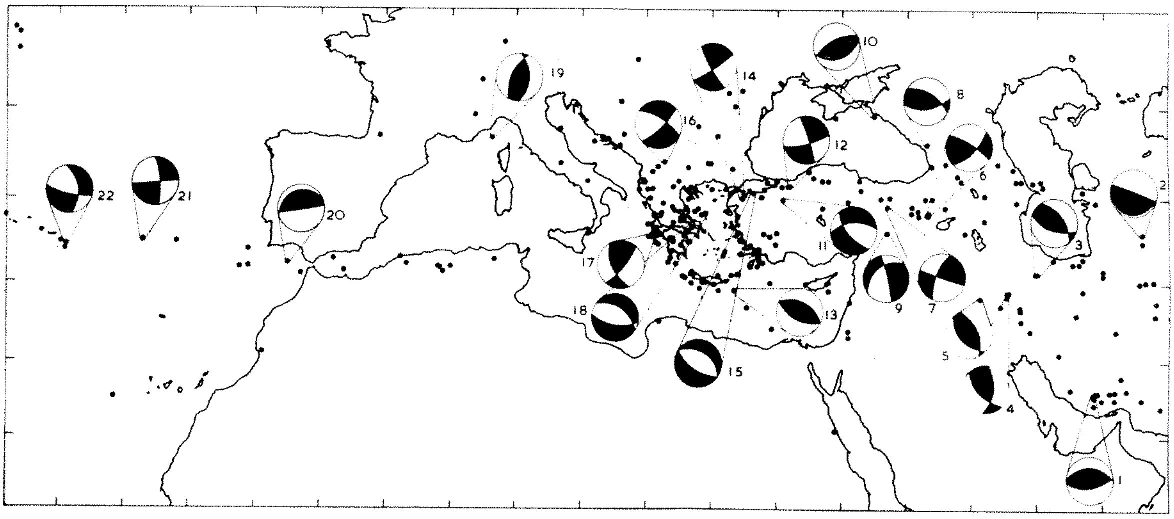

Fig. 2. Epicentres of earthquakes since 1925 whose magnitude was greater than about 6 are shown as solid dots. The focal mechanisms of some of these shocks are represented by balloons which show the lower hemisphere in stereographic projection with the compressional quadrants black. The North Anatolian Fault and the Azores–Gibraltar ridge and its eastward extension are more obvious than in Fig. 1, but otherwise the seismic activity resembles that of the shorter period.

This process is believed to produce wide belts of fold mountains.

Fig. 1 shows the region selected, which extends far beyond the boundaries of the Mediterranean Sea. The epicentres of earthquakes are plotted, taken from the United States Coast and Geodetic Survey between 1961 and 1967. It is clear from the seismicity (Figs. 1 and 2) that many small plates occur in the Mediterranean, but in two places, the Caucasus and the Azores–Gibraltar ridge, intervening plates are absent. These two special cases greatly simplify the problem of understanding the tectonics elsewhere. The seismicity of continental areas shows that such simple boundaries often exist[13], and it is essential to choose a region sufficiently large to include them. If, for instance, this study had been restricted to the Mediterranean itself it is doubtful if any progress would have been made.

There are now several methods of determining the position of plate boundaries and the magnitude and direction of the relative slip vectors between adjacent plates. Only epicentres and focal mechanisms of earthquakes are used in this study; thus the shape and direction of motion of the plates can be obtained, but not the rate of slip[5,8]. Figs. 1 and 2 show the position of the plate boundaries in this region. The seismicity associated with the Azores–Gibraltar ridge marks the junction between the African and the European plates, but east of Sicily the boundary is no longer sharp and the focal mechanisms do not reflect the motion between Europe and Africa. The focal mechanisms in Fig. 2 are in stereographic projection. They are projections of the lower hemisphere onto a horizontal plane, with the compressional quadrants shown as black regions. Thus right handed strike slip faulting gives a solution like 21 if the faulting is on an east–west fault, normal faulting gives a solution like 15, and overthrusts solutions like 13. Solutions like 11 and 17 are combinations of normal and strike slip faulting, and of thrust and strike slip faulting respectively. All solutions except 2, 4, 11, 17 and 21 were obtained by reading the vertical long period seismograms obtained from the World Wide Network of Standardized Stations. No such solutions could be obtained for the five earthquakes just mentioned because they took place before the network was installed. They were obtained by plotting all available readings in an equal area projection, then fitting nodal planes. About 100 solutions have now been obtained in this area, and will be published individually elsewhere. The plate boundaries and motions described account for most of these mechanisms, except those obtained for earthquakes on the Greek mainland. Here the deformation is rather complicated, and may be related to the motion of plates too small to be resolved by the seismicity. The solutions in Fig. 2 are some of the best obtained, and are chosen for this reason alone.

Only three plate boundaries of any importance enter the area, and therefore only three major plates are involved in the tectonics. These plates are the African, Eurasian and Arabian plates, and the boundaries between them are the Azores–Gibraltar ridge and its extension across North Africa, the Red Sea and the Alpide zone in Iran (Fig. 4). The line of earthquakes extending from Sicily to the Azores across North Africa out into the Atlantic following the Azores–Gibraltar ridge marks the boundary between the African and Eurasian plates. Several large earthquakes have occurred on this boundary, of which the most famous was the Lisbon earthquake of 1755. Two more recent earthquakes, in 1942 and 1969, were of magnitude 8 or more. The pole of relative motion between these plates has been calculated to be at 9° N, 46° W by Le Pichon (misprinted in his original paper). This pole requires the motion between Africa and Eurasia to be strike slip at the Azores, changing to overthrust south of Spain and in North Africa. Such motion agrees excellently with the fault plane solutions in Fig. 2, and with some other less good solutions in North Africa. Both the pole position and the fault plane solutions show that the motion between these plates is strike slip with a small amount of extension near the Azores. Because the pole of rotation is close to the area, the direction of motion changes rapidly going eastward along the Azores–Gibraltar ridge. The fault plane solutions show this change in more detail (Fig. 2), with the strike slip faulting changing to overthrusting in the Straits of Gibraltar and across North Africa. This remarkable variation is rare, and studies of this boundary are therefore of considerable interest. Also few examples of plate boundaries are known with slow consumption rates, and the features associated with such structures have not been studied in any detail. It is surprising that few intermediate depth earthquakes are associated with this boundary. Those beneath the Tyrrhenian Sea are unlikely to be directly related to the motion of Africa towards Europe because they are confined to a local area, and also because they are within a slab which dips west[14], or at right angles to the direction of motion of Africa.

The seismicity east of Sicily does not show whether the plate boundary between Africa and Europe extends across the south end of the Adriatic to join the Cretan Arc, or whether the motion is taken up by the activity in Italy and Yugoslavia. A dramatic change occurs in the eastern Mediterranean. The seismic activity of Albania, southern Yugoslavia, Greece and Turkey is very much greater than that of the western Mediterranean. Large earthquakes of magnitude greater than 7 are common, and are often associated with slip on major faults. Also the fault plane solutions become complicated (Fig. 2). This change is not the result of an active plate boundary joining that between Africa and Europe, nor is it the effect of the opening of the Red Sea[15]. The cause of this local increase in activity is the existence of two small rapidly moving plates, one containing the Aegean, part of Greece, Crete and part of western Turkey, the other containing most of Turkey and Cyprus. These plates will be called the Aegean and Turkish plates respectively. The motion between the Aegean and the Eurasian plate is shown by fault plane solutions such as 11, 14, 15 and 18. These solutions vary between strike slip and normal faulting. They therefore permit the fault plane to be distinguished from the auxiliary plane, and hence determine the slip vectors. These solutions show that the Aegean plate is moving towards the south-west relative to the European plate, producing extension and strike slip on the boundary between them. This boundary crosses from the Sea of Marmara across the northern Aegean, and probably reaches Greece between the island of Evvoia and the mainland. A deep trough exists in this part of the Aegean which reaches to a depth of 1,500 m and is associated with large magnetic anomalies[16]. The fault plane solutions suggest that this trough has been produced by extension of the crust, associated with large basic intrusions. Therefore from the point of view of plate tectonics this feature is a ridge. It is, however, very different from most oceanic ridges because the relative motion between the two sides is partly right-handed strike slip and partly extension, and also because the total extension is comparable to that of the East African Rift, rather than the major oceanic ridges. The present seismicity in the northern Aegean does not follow this trough, though the faulting is of the type which could produce it.

The southern boundary of the Aegean plate is moving south-west relative to the African plate, and is overthrusting the Mediterranean Sea floor. The direction of motion is given by solutions 13 and 17 (Figs. 2 and 4) and also by the existence of intermediate earthquakes beneath Greece and the southern part of the Aegean (Fig. 3). This plate boundary has several other features which show

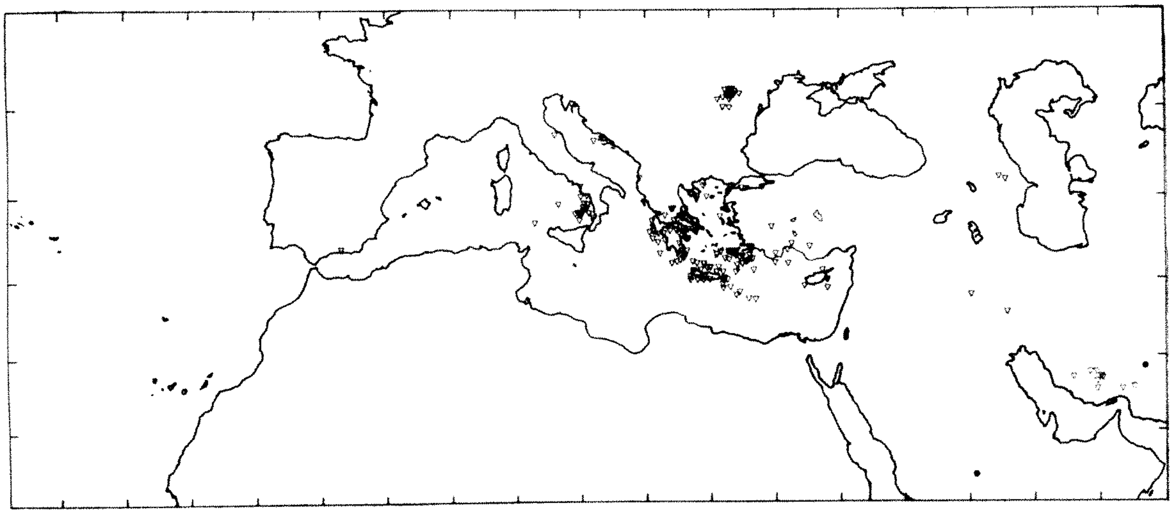

Fig. 3. Epicentres of all earthquakes with foci below 70 km depth which occurred since 1925. The active regions are localized and, if the concepts of plate tectonics are correct, mark the sites of consumption of lithosphere active during the last 10 m.y. (refs. 11 and 24).

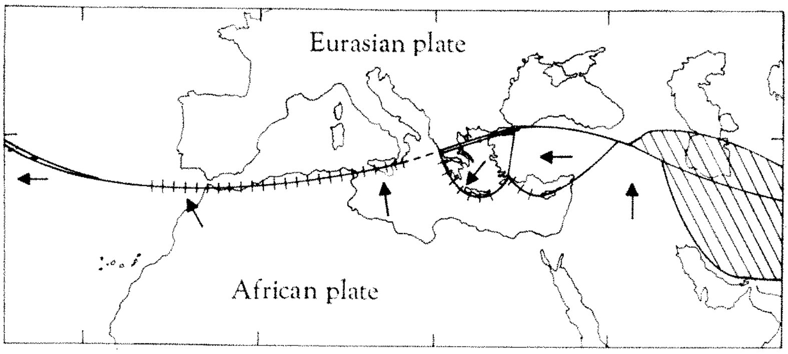

Fig. 4. Approximate positions of plate boundaries at present active, with arrows marking the directions of motion relative to the Eurasian plate. Boundaries creating lithosphere are shown with a double line, boundaries consuming plates with short lines at right-angles to them. The cross-hatched region in Eastern Turkey and Iran is seismically active throughout. Fault plane solutions here are all overthrusts (Fig. 2), and show that the crust is being thickened all over this region. Most major shocks within the cross-hatched area occur on major active faults mapped by Wellman[26] from aerial photographs and shown as solid lines.

that it is indeed a trench. Active and dormant andesite volcanoes occur in Greece and in several of the Aegean islands, of which Santorini is the most famous. Several surveys have detected a large negative free-air gravity anomaly[17,18] and deep depression in the sea floor extending from Zakinthos to Rhodes[19]. Also Ryan[20] has demonstrated the existence of thrust features in the seismic reflexion records of sediment deformation. All these observations show that the sea floor south of the Cretan arc is being overridden from the north-east and sinks beneath the Aegean Sea.

The seismicity of the Turkish plate and the fault plane solutions show that it is moving approximately due west relative to both Europe and Africa. The northern boundary of the plate is the North Anatolian fault, which is an active east–west right-handed strike slip fault whose slip rate has been estimated[21] to be 11 cm yr^{-1}. It is continuous with the northern boundary of the Aegean plate, which takes up the motion towards the west. Many earthquakes have occurred on this fault throughout northern Turkey, and many have produced surface displacements[22,23]. There is therefore no ambiguity between the fault plane and the auxiliary plane. The southern boundary of the Turkish plate is not well defined by the seismicity, and only one poor solution, No. 9, has been obtained on it. It seems to join the southern boundary of the Aegean plate south of south-west Turkey, and to run south of Cyprus into the Gulf of Alexandretta to join the North Anatolian fault east of Erzincan. The motion across this boundary is mostly left-handed strike slip, probably with some overthrusting in the south-west. The surface features and fault plane solutions associated with the North Anatolian fault show a striking change east of Erzincan. West of this point the fault is strike slip and has a surface trace which closely resembles that of the San Andreas. To the east, however, there is no distinct trace, and the fault plane solutions show a large component of thrusting, with the north overriding the south. Solutions in the Caucasus and further south show that the horizontal projection slip vector is north–south, and the fault plane solutions are overthrust. In this region the seismic activity is confined to a narrower belt than it is either to the east or west, though it is still spread over a wider belt than is common in the oceans. Thus in eastern Turkey, the Caucasus and western Iran the fault plane solutions show that Africa and Arabia are moving northwards, and though the motion is taken up on several faults, there are no small plates moving rapidly east or west. Thus the existence of the Anatolian fault and other large strike-slip faults is caused by the rapid motion of the Turkish plate westward. The geometry and motions of both the Turkish and Aegean plates are both complicated and surprising. A possible explanation depends on the difference in behaviour between continental and oceanic lithosphere. Continental material is too light to sink through the mantle, and therefore cannot vanish[24]. In parts of the Alpide belt such as Iran and the Caucasus, large thicknesses of continental rocks have accumulated, and considerable work must be done against gravitational forces to further thicken the continental crust. No such work need be done if oceanic lithosphere can be consumed, rather than continental lithosphere thickened. This is indeed the result of the motion of the Aegean and Turkish plates, which avoids further overthrusting in Turkey and instead consumes the Mediterranean Sea floor in front of the Cretan arc. Thus the present motions are such as to minimize the work which need be done to move the African Plate towards the Eurasian. This particular mechanism may also account for the existence of localized sources of intermediate earthquakes, such as those beneath Roumania and the Hindu Kush[13]. The earthquakes in these regions occur in slabs within the mantle which closely resemble those beneath island arcs[25]. These sources are puzzling because both are now overlain by continental crust, yet all other sources of intermediate earthquakes occur within a slab of what was originally oceanic lithosphere. The process at present taking place in the eastern Mediterranean is producing a localized source of intermediate earthquakes by rapid underthrusting beneath the Cretan arc. A similar mechanism could consume remnants of oceanic crust in other regions, such as the southern part of the Caspian Sea. This process is only possible if small plates of continental lithosphere are easily formed to consume oceanic crust in a limited region. It is therefore important to search for geological evidence for the previous existence of such plates in Roumania and the Hindu Kush.

The tectonics from the Caucasus to the eastern limit of the area appears to be considerably simpler than that further west. All fault plane solutions east of 44° E are overthrust, some with small components of strike slip faulting. Many solutions contained only one dilatational reading, always from a close station; and if the focus was taken to be in the mantle it was rarely possible to draw two orthogonal planes separating the compressions from the dilatations. Because several of the earthquakes in question produced surface breaks on faults[26,27], this difficulty is not caused by an explosive type of source mechanism but by refraction of the rays at the Moho or above. If the foci were taken to be in the crust, with a velocity of 6·8 km s^{-1}, all mechanisms could be described by a double couple source with the fault plane at right angles to the auxiliary plane. There is, however, at present little accurate information about the deep crustal velocity structure in this region, and therefore none of these mechanisms is well determined. In particular, most could have a larger component of strike slip than shown in Fig. 2.

All solutions in southern Russia and Iran show that this part of the Alpide belt is taking up the motion of India and Arabia towards Asia by overthrusting over a wide belt from southern Iran to the central Caspian. Most earthquakes are associated with the major active faults described by Wellman. The sense of displacement on surface faults may be used to determine the fault plane and the auxiliary plane, and hence to obtain slip vectors. The resulting vectors show that the motion direction varies little from 35° E over the entire region. This direction is little different from 15° E, the direction to be expected from the Arabia–Eurasia pole at about 25° N, 12° W. Thus the deformation of Iran and southern

Russia appears to be much simpler than that of the Eastern Mediterranean. The result of present activity in this part of the Alpide belt is to thicken the continental crust over a wide region. Though Gutenberg and Richter[28] show a few intermediate earthquakes in southern Iran, the deepest shocks with reliable depths from 1962 to 1967 were at about 100 km. There are not sufficient stations in this area to produce reliable depth estimates if, as seems probable, there are high velocity slabs still present in the mantle. Thus there is little evidence for any destruction of continental lithosphere throughout this region.

This account of the tectonics of the Mediterranean and Western Asia shows that the concepts of plate tectonics provide a useful description of continental tectonics. It also suggests that the boundaries of continental plates often may be complicated by the existence of small rapidly moving plates whose motion is not simply related to the motion of any of the major plates involved. A more complete account containing about 100 fault plane solutions on which this study is based is to be published elsewhere.

The relative motion between the plates on each side of the East African Rift Valley can be obtained from the opening of the Red Sea and the Gulf of Aden. The calculated direction of relative motion agrees well with fault plane solutions for earthquakes north of the equator.

THE Red Sea and the East African Rift Valley were the first major features to be recognized as having been produced by extension of the Earth's crust[1,2]. Normal faulting along the sides of the Rift Valley during earthquakes shows that this motion still continues[3]. As the seismic activity of the Indian Ocean ridges is continuous with that of the East African Rift (ref. 4 and unpublished work of Fairhead), the African Rift served as a model for oceanic rifts. It was therefore studied in some detail because the significance of rifting in the oceans was not at first understood.

It is somewhat surprising that this situation is now reversed. Modern theories and oceanographic methods have been so successful that the evolution and tectonics of the ocean floor are now much better studied and understood than similar processes on land. It is therefore now possible to construct an outline of the movements involved in the formation of the Rift Valley from the history of the surrounding ocean basins. Such a reconstruction is attempted here, and the results are in general agreement with studies of the Rift Valley itself. Perhaps the principal result of this and other studies of this region is that, though the Rift is still of great interest, it is not of global importance. The discussion below demonstrates that the extension by which it was produced is everywhere less than 65 km, and probably took place in the last 20 million years. This motion is small compared with 3,000 km in the East Central Pacific during the same period, or even with 500 km in the North Atlantic.

The seismicity of the Red Sea, Gulf of Aden and the East African Rift (Fig. 1*a*) shows that three plates meet at the south end of the Red Sea. These plates we will call the Arabian, Nubian and Somalian Plates, and will only consider the relative motions between these plates in Africa north of the equator, in the Red Sea and Gulf of Aden, and in Egypt, Jordan and Israel. If the motions between the Arabian plate and the Somalian and Nubian plates respectively can be determined, the motion between the Somalian and Nubian plates may be calculated from the postulates of plate tectonics[5,6]. The results of such calculations are shown in Fig. 1*b*, where the heavy double lines mark the three extensional plate boundaries and the arrows show the relative motion between the plate on which the arrow lies and the adjoining plate. A junction between three ridges is possible without compression of any of the plates involved.

The motion between the Arabian and Somalian plate was first determined by Laughton[7] from the strike of transform faults in the Gulf of Aden. He used them to fit the coast of Africa to that of Arabia, and showed that the geological structures on each side then matched remarkably well. The seismicity and fault plane solutions for earthquakes[3,4] in the Gulf and the magnetic lineations agree with the direction of motion proposed by Laughton.

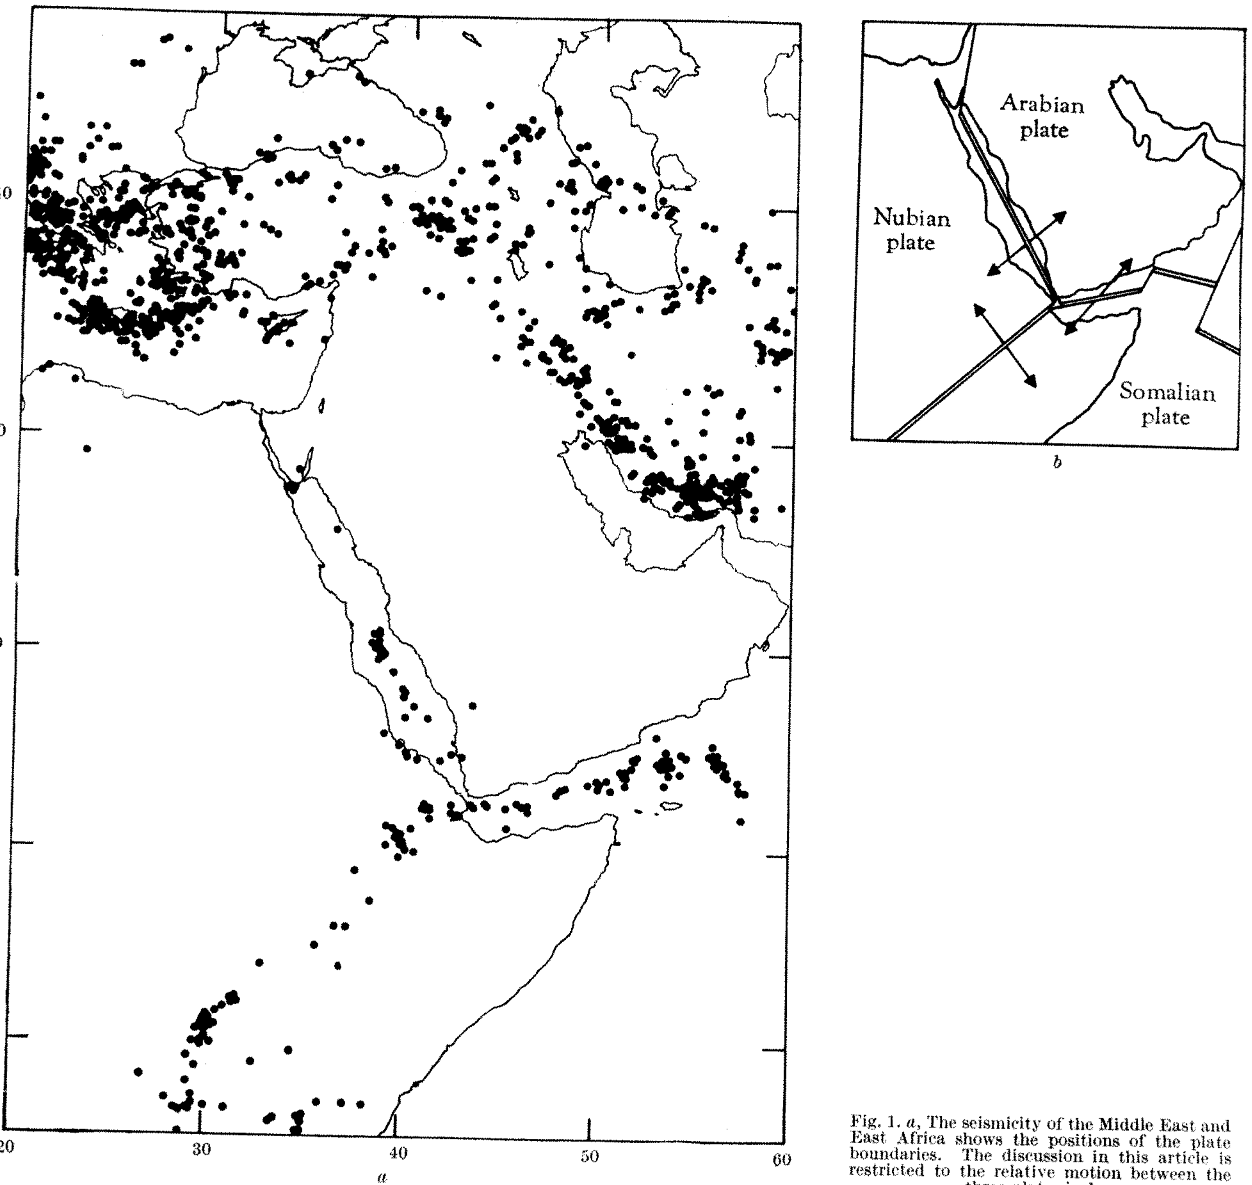

Fig. 1. *a*, The seismicity of the Middle East and East Africa shows the positions of the plate boundaries. The discussion in this article is restricted to the relative motion between the three plates in *b*.

The pole of rotation of the Arabian plate relative to the Somalian plate may be obtained either from the transform faults and magnetic lineations[9], or by fitting the 500 fathom contours on each side of the Gulf. The pole positions from the two methods are within a degree of each other, and the pole from the fitting at 26·5° N, 21·5° E, with a rotation angle of 7·6° is used throughout this discussion. The resulting fit is shown in Fig. 3, and demonstrates how accurately the two sides match. Neither Socotra nor Mount Error, however, both of which are probably continental fragments, fit back onto Arabia. The separation of Africa must therefore have involved a progressive penetration of the Carlsberg Ridge into the continent.

In contrast to the Gulf of Aden, the structure and evolution of the Red Sea are much more controversial. Though Wegener[9] noticed that the coast lines on each side fitted together, it seemed unlikely for several reasons that the whole of the Red Sea was underlain by oceanic crust. Bathymetric surveys showed that the sea floor consisted of shallow marginal seas on each side of a deep main trough. Also gravity surveys had shown almost no free air anomaly. These observations suggested to Girdler[10] that the main trough was underlain by continental rocks and that only the axial trough was underlain by sea floor. This suggestion was supported by measurements of the magnetic anomalies, which are of large amplitude above the axial trough but almost absent elsewhere.

These arguments became less convincing when the Red Sea was drilled in search of oil, and thicknesses of up to 5 km Miocene evaporite were found[11]. This result suggested that the marginal seas were directly underlain by thick beds of evaporite and not by continental crust. Seismic results also strongly supported such a model. Tramontini and D. D.[12] shot a large number of seismic refraction lines parallel to the axial trough and showed that the marginal seas consisted of 3 to 5 km of material with a seismic velocity of 4·3 km s^{-1} overlying the basement. Because the basement had a velocity of 6·6 km s^{-1} they suggested that it was oceanic crust rather than subsided continental material. They also showed that such a structure is compatible with the gravity observations. If a large part of the Red Sea is indeed underlain by oceanic crust, as these observations suggest, the only remaining difficulty is the absence of magnetic anomalies of substantial size in the main trough. Calculated anomalies for this latitude and spreading rate have an amplitude of 100 γ or less, however, and anomalies of this magnitude could be present in parts of the seas. Thus there is now considerable evidence that the entire Red Sea trough has been formed by the movement of Arabia away from Africa, and therefore that the pole and rotation angle

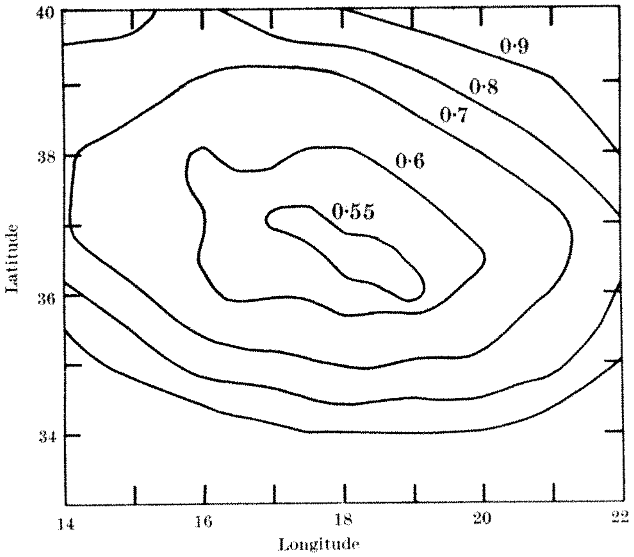

Fig. 2. Contours of the total misfit area (overlap and gap) in square degrees for the Red Sea as a function of the latitude and longitude of the rotational pole. The rotation angle is adjusted at each point to minimize the misfit.

for the separation can be obtained by fitting together the coast lines. It is fortunate that this is the case, because all bathymetric contours are governed by coral reefs and by salt accumulations, and therefore cannot be used for this purpose.

The two coast lines north of 15° N were fitted by choosing a latitude and longitude for the rotation pole, then rotating one until the total misfit area, without respect for its sign, was minimized. The procedure was then repeated for a different choice of pole position until a contour map of the misfit area as a function of pole position could be drawn. All programmes used rotation matrices and vectors, which are both easier to use and more economical of machine time than programmes which use spherical geometry. The total area of misfit, rather than the fitting criterion of Bullard, Everett and Smith[13], was used to avoid difficulties which occur with their scheme if parts of the coast lines are small circles about the relative rotational pole, and also to avoid the weighting problems which occur when the coasts are close to the rotation pole. In this case, however, the same pole at 36·5° N, 18° E, off western Greece, is obtained by both methods (Smith, personal communication). The contours of the misfit area as a function of pole position (Fig. 2) show that the minimum is a linear trough surrounded by a rather steeply sloping bowl. No local minima were found, and the shape of the surface suggests that any that may exist must occur within the narrow trough, and are therefore unimportant.

Fig. 3 shows the resulting fit of the Red Sea coast lines. As previous authors have observed, the fit is remarkably good, and it is hard to distinguish the rotated coast line of Africa from that of Arabia. Because it is difficult to imagine any geological process other than splitting which could produce such a remarkable correspondence between opposing coast lines, this fit therefore also suggests that the whole of the Red Sea trough has been produced by the separation of Arabia from Africa. At the south end of the Red Sea the two coast lines converge, and therefore overlap when the northern part is closed. This discrepancy suggests that Afar depression has been largely created from mantle materials during the separation, and recent aeromagnetic evidence[14] has supported this view.

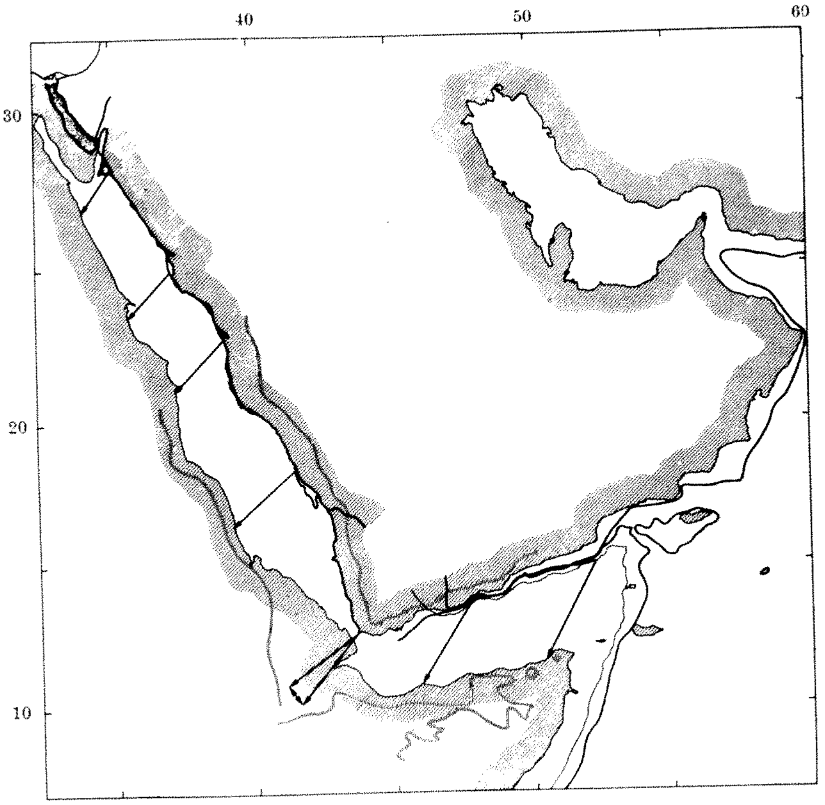

Fig. 3. The fit of the Red Sea coast lines and the 500 fathom contours in the Gulf of Aden. The arrows show the motion of the Nubian and Somalian plates relative to the Arabian plate during the opening of the Red Sea and Gulf of Aden. The difference between them gives the motion on the East African Rift. The narrow cross-hatched lines mark the 1,000 m escarpment on land.

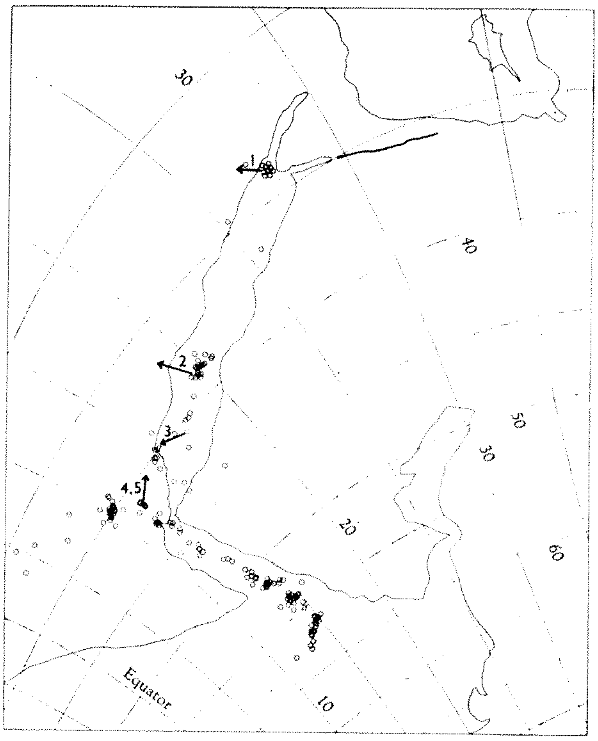

Fig. 4. Oblique Mercator projection of the Red Sea with axis 36·5° N, 18° E, the pole for the best fit of coast lines. The three slip vectors from the fault plane solutions in Fig. 5 are approximately horizontal and parallel to the top and bottom of the figure. The instantaneous motion is therefore along small circles with respect to the finite rotational pole.

The pole determined from the fit of the coast lines is not necessarily the present instantaneous pole of rotation between the Arabian and Nubian plates, nor need the motion between the two have been steady. There is, however, some evidence that neither the relative pole nor the rotation pole between the two plates differs greatly at present from the mean pole. Magnetic anomalies at 16° N on the axis of the Red Sea suggest that the spreading rate is about 1 cm yr^{-1} on each side[15]. If the separation occurred in the Miocene, or about 15 million years ago, and drift were continuous, this rate of drift would produce a separation of 300 km, or close to that observed. It must, however, be admitted that the identification of anomalies in this region is somewhat in doubt.

Fault plane solutions for earthquakes in the Red Sea permit an independent test of the accuracy of the instantaneous pole position, though not of the spreading rate. Fig. 4 is a map of the Red Sea and surrounding regions in an oblique Mercator projection with the relative rotational pole as the Mercator axis[5]. Because the relative motion between plates must always take place along small circles about the relative rotational pole, this Mercator projection has the property of making all rotations about this pole become translations along straight lines parallel to the top and bottom of the map. It is therefore possible to close the Red Sea by sliding one coast horizontally against the other with no rotation. The present motion between the Arabian and Nubian plates may be obtained from fault plane solutions of earthquakes in the Red Sea. Though these are rarely large enough to permit reliable solutions to be obtained, three such earthquakes have occurred in this region since the World Wide Long Period Network was installed. One of these, the slip vector of which is numbered 3 in Fig. 4, was obtained by Sykes[3]. This solution was not well controlled (Fig. 5) and the direction of the slip vector is uncertain by perhaps 30°. Fig. 5 shows solutions 1 and 2, both obtained from reading the long and short period records, from standard stations alone. Solution 1 shows normal faulting, and it is impossible to decide which is the fault plane and which the auxiliary. Fortunately, no such distinction is necessary if the horizontal projection of the slip vector alone is required, because it must lie at right-angles to both planes. The location of this earthquake at the south end of the Gulf of Suez means that it is impossible to decide whether it is caused by the separation of Arabia from Africa or by the movement of Sinai from Africa. Because, however, the difference between the two slip vectors is within the experimental error for strike of the slip vector, solution 1 may be used to determine the motion between the Arabian and Nubian plates. Solution 2 is a strike slip solution, and it is therefore necessary to determine which plane is the fault plane. If the plane marked "fault" in Fig. 5*b* is chosen, the resulting slip vector (Fig. 4) is consistent both with the direction of opening of the Red Sea and with the slip vector from solution 1. Neither remark is true for the other possible choice, which is therefore excluded. Though the slip vector for solution 2 is consistent with the direction of spreading, the mechanism is peculiar. There is no feature on the sea floor close to the earthquake to suggest that the ridge is offset by a transform fault near this earthquake. What is perhaps even more surprising is that the mechanism corresponds to right-handed slip on a fault, or a left-handed offset of the ridge axis. This is in the opposite sense to that suggested by the general trend of the Red Sea relative to the pole of rotation of Arabia relative to Africa (Fig. 4).

These three solutions are consistent with the hypothesis that the present pole for the opening of the Red Sea is the same as the pole obtained from fitting the coast lines, though none of these solutions is sufficiently good to provide a rigorous test of this hypothesis. Until more

earthquakes occur, the fitting pole provides the best instantaneous pole for this area.

No use has yet been made in this discussion of the work done by Quennell[16], Freund[17,18] and others on the evolution of the Dead Sea rift. Their careful work has established that there has been close to 110 km left lateral motion on the Dead Sea fault system since the Miocene. The eastern margin of the Dead Sea Valley is shown as a heavy line in Fig. 4. As it is not parallel to the top and bottom of the figure it cannot be a transform fault between the Arabian and Nubian plates. This result is supported by the magnitude of the displacement on the Dead Sea fault, which is 80 km less than the 190 km required at this latitude to open the Red Sea if the present shore lines were once in contact. This difference must be taken up on some other structure, and the only possible choice is the Gulf of Suez and the low lying land to the north. The whole region is a large graben which has been filled with up to 3 km of evaporites[19]. The basement which occasionally outcrops is Pre-Cambrian in places, and not oceanic crust. It is possible to reconstruct the north end of the Red Sea by rotating Africa towards Arabia to close the Red Sea, then sliding Sinai 110 km northwards along the Dead Sea rift. The resulting reconstruction closes the Gulf of Suez (Fig. 3). Fig. 6 shows the motions of Arabia and Africa relative to Sinai in more detail, and demonstrates that the extension required across the Gulf of Suez is between 60 and 90 km. The reconstruction leaves a gap of 20 to 30 km between exposures of unfaulted Pre-Cambrian basement on each side of the Gulf. If the extension occurred by normal faulting over a region perhaps originally 50 km wide, crustal thickness would decrease from 30 km to 15 km. A difference in elevation of about 3 km would still remain after isostatic compensation. This difference is comparable with the thickness of salt found in bore holes. Girdler *et al.*[20] have suggested a similar mechanism to account for the gravity field in East Africa. They, however, suggested that the process occurred by necking rather than by faulting. Rocks fail by brittle fracture at the temperatures which occur in a Pre-Cambrian crust, so extension should cause normal faulting. There is no obvious reason why extension in the Gulf of Suez takes place by this process rather than by the formation of ocean floor. Perhaps the activation of many normal faults depends on the existence and orientation of existing basement faults. The long history of activity in the Gulf of Suez suggests that many such faults must have existed.

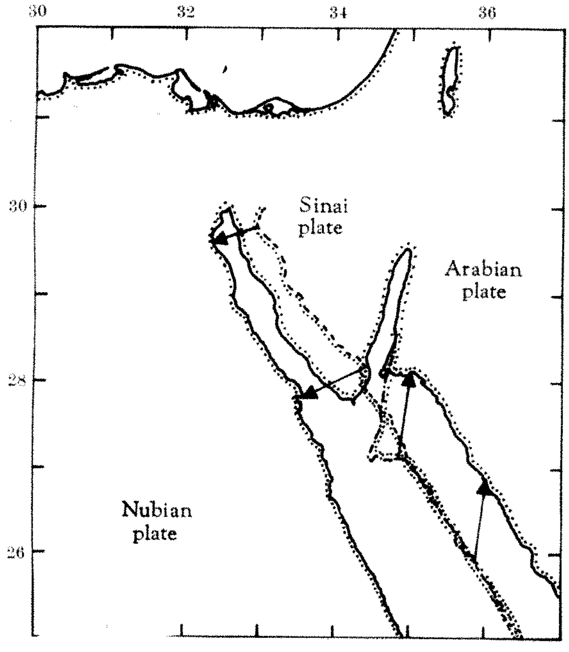

Fig. 6. Relative motion between the Sinai plate, taken to be fixed, and the Arabian and Nubian plates is shown by the arrows.

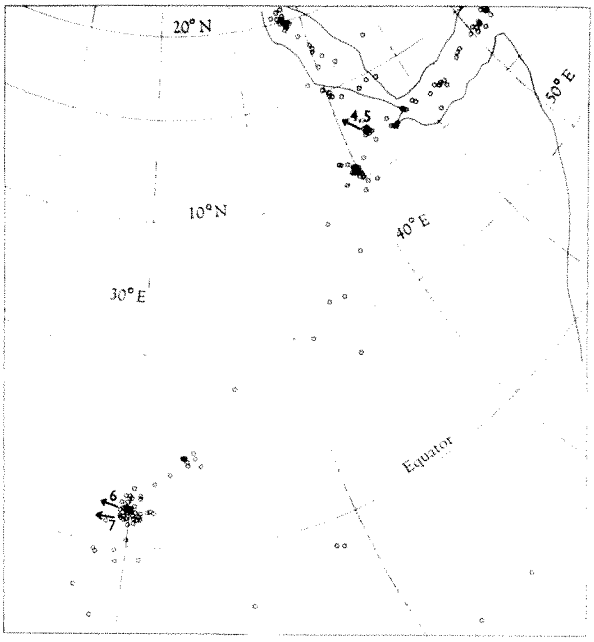

Fig. 7. Oblique Mercator projection of East Africa with axis at 8·5° S, 31° E. As in Fig. 4, the slip vectors are approximately parallel to the small circles about this pole which form the top and bottom of the figure.

This discussion of the opening of the Red Sea shows that there is no conflict between geological evidence and the evolution suggested. The poles of opening and rotation angles for the Red Sea and Gulf of Aden may therefore be combined to obtain the pole and angle of rotation between the Nubian and Somalian plates. Because the relative rotation angles are all small, a good approximation to the pole for the rift may be obtained by adding the other two rotations as vectors. The resulting pole is at 8·5° S, 31·0° E, with a rotation angle of 1·9°, and the opening on the rift that has taken place varies from 65 km in northern Ethiopia to 30 km in Kenya. It is doubtful whether the Rift Valley south of the equator has opened about this pole because the seismic belt which runs between Madagascar and the mainland probably joins the Rift Valley in Tanzania. These extensions are of the same order of magnitude as those estimated from field geology[21].

The mean pole and rotation angle need not coincide with the instantaneous pole for the rift. As in the case of the Red Sea, however, the coincidence of the two poles may be tested by using fault plane solutions. Fig. 7 is a map of the seismicity of the Rift Valley in Mercator projection with the Nubian–Somalian rotational pole as axis. The slip vectors from four earthquakes on the Rift and its extension, numbers 4, 5, 6 and 7, are approximately parallel to small circles, and therefore suggest that the present pole is close to the mean pole of opening.

Solutions 4 and 5 (Fig. 8) both show strike slip faulting. There is, however, no ambiguity about which nodal plane is the fault plane, because the surface displacement which accompanied these earthquakes was along a fault striking N 40° W (ref. 22). Solution 6 shows normal faulting and was published by Sykes[3]. Solution 7 was published by Banghar and Sykes[23], and was an aftershock of 6. If its mechanism is taken to be the same as 6 the slip vector is well determined. Earthquake 6 also produced a surface break which again decides the orientation of the slip vector. No other solutions using long period seismograms have been discovered. Solutions 4, 5, 6 and 7 show that

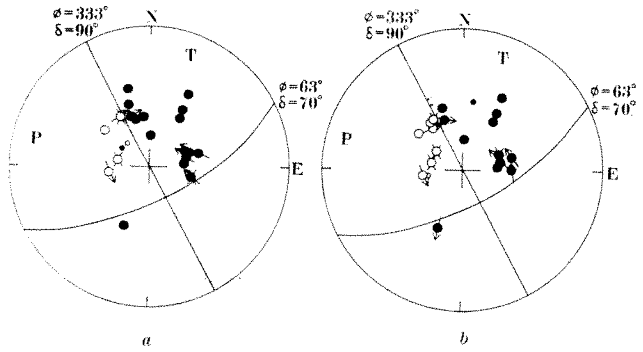

Fig. 8. *a*, Fault plane solution for earthquake 4 in Fig. 7 on March 29, 1969, at 12·0° N, 41·2° E. *b*, Fault plane solution for earthquake 5 in Fig. 7 on April 5, 1969, at 12·2° N, 41·3° E. The fault plane solution for earthquake 6 was published by Sykes[3], that for 7 by Banghar and Sykes[23].

the strike of the horizontal projection of the slip vectors is consistent with the pole obtained here.

The Mercator projection in Fig. 7 suggests various interesting possibilities concerning the structure and evolution of the Rift Valley. From the equator to about 5° N the seismically active region is offset in a right-handed sense, and therefore earthquake mechanisms in this region should show a combination of left-handed strike slip and normal faulting. Between 5° N and the Afar depression the motion vector is almost at right-angles to the seismic zone, and therefore normal faulting should be dominant. It is, however, surprising that the two solutions 4 and 5 for earthquakes within the Afar depression (Fig. 8) are consistent with the pole obtained for the Rift further south, and therefore that the boundary between the Arabian and Nubian plates does not cross the Afar depression but joins the Rift boundary east of the Gulf of Tadjura at the west end of the Gulf of Aden. The earthquakes, the solutions of which are shown in Fig. 8, must therefore lie on a right-handed transform fault joining the Rift Valley to the Gulf of Tadjura.

If the position of the ridge axis jumped from the western side of the Danakil horst to its present position in the Straits of Babel Mandeb a piece of what was the Arabian plate would be left attached to the Nubian plate. These speculations could therefore account for both the seismicity and the existence of the Danakil horst[7]. This elevated region in the Afar depression consists of Jurassic and older rocks similar to those of Arabia, to which it was presumably once attached. Further studies of the seismicity of the Afar depression should provide a test of this hypothesis, which is only consistent with the seismicity in Fig. 1 if a transform fault crosses the northern part of the Afar triangle.

This study shows that the concepts of plate tectonics can be useful where plates are separating at millimetres a year, and the total relative motion of which has been between 30 and 300 km. These rates are at least an order of magnitude smaller than those of most major plate boundaries in oceanic regions. This success is somewhat surprising, and may be due to the exceptional rigidity of the Pre-Cambrian shield areas cut by these active structures. This study also strongly suggests that the tectonics of some parts of continents can be described by the theory that has been so successful beneath the oceans. Several interesting features of this area deserve further study. Mount Error and Socotra do not fit against Arabia when the Gulf of Aden is closed, and therefore were broken off from Africa before the Arabian plate. The surrounding sea floor should have recorded the processes which take place when an existing ridge extends beyond its limiting transform fault, which in this case was probably the Owen fracture zone.

If the suggested evolution of the Afar depression is correct, this area contains one of the few ridges which is known to have jumped and the only such example yet discovered on land.

Another remarkable feature of the region is the trend of the magnetic anomalies in the Gulf of Aden[24]. The magnetic lineations are not at right-angles to the transform faults, and therefore the ridge which formed them was spreading obliquely to the motion direction between plates. Few other examples of such ridges are known. Several rather unconvincing suggestions have been put forward to explain why most ridges and magnetic lineations are at right-angles to their transform faults. Studies of the Gulf of Aden might resolve this problem.

Finally, we wish to point out two misunderstandings which have appeared in several previous papers on this region. The first involves rotations of plates on a sphere. Various authors have maintained that the opening of the Red Sea can be described by a translation northwards combined with a rotation, often taken to be a pole in Sinai. This description of the motion is incorrect, because no translations are possible on a spherical surface. These authors are therefore producing the displacement by two successive rotations. We prefer to use one rotation. Furthermore, any attempt to obtain a pole for the opening of the Rift by the method used here requires the single pole and rotation angle which open the Red Sea, and cannot be obtained from either of the other two poles alone.

The other confusion which has occurred involves the relationship between the opening of the Red Sea and Gulf of Aden and the active Alpide belt to the north. Fig. 1 shows the seismicity recorded by the United States Coast and Geodetic Survey between 1961 and 1968. It is clear that earthquakes originating in Iran, Turkey and Greece during this interval are much more frequent than those in the Red Sea and Gulf of Aden. Estimates of the slip rate between the plates in Turkey and Iran vary from 10 to 20 cm yr^{-1}, or more than an order of magnitude greater than those involved in the Red Sea. Also the high seismicity of Iran continues westward into Turkey and is unaffected by meeting the northward extension of the Dead Sea rift. Thus crustal generation between Arabia and Africa is quite unable to account for the seismicity of the region to the north.

We thank Dr R. L. Parker for help in producing the diagrams. This research was in part supported by the US National Science Foundation.

Flash spectra of the total solar eclipse throughout all its phases have been obtained in the extreme ultraviolet for the first time.

AN Aerobee 150 rocket was launched at 18 h 36 m 15 s UT on March 7, 1970, into the total solar eclipse then passing over the established NASA launch range at Wallops Island, Virginia. The vehicle successfully completed its programmed pointing manoeuvres and, at 18 h 39 m 32 s UT, entered the umbra at an apogee of 142 km. A sequence of fifty spectra were recorded over a period of 180 seconds in the range 850 Å–2150 Å. The spectra are spatially resolved and show images of the eclipse in each spectral line. Each frame refers to the particular phase of the event as seen from the rocket at the time of exposure. The observed time sequence of the eclipse is determined by the dynamics of the Sun–Moon–rocket system and the fifty frames cover a range starting from before second contact, that is, the point of total obscuration of the visible disk, to near mid-totality. This article is a summary of the experiment.

The ideal trajectory for this type of experiment is one that is parallel to the direction of motion of the eclipse shadow and central within it. Within the constraints imposed by the vehicle performance and the location of this eclipse path relative to the range, the optimum configuration for the present experiment was determined and involved a trajectory approximately at right angles to the line of motion of the 120 km wide shadow cone. As the basic objective of the flight was to record the ultraviolet flash spectrum of the chromosphere, the conditions of launch were chosen, within the constraints, to yield second contact at rocket apogee and so minimize the effects of atmospheric absorption. Further factors that were considered in determining the final conditions of flight were: (i) a minimum apparent scan rate of the lunar limb, (ii) a minimum in apparent rotation of the line of centres throughout the data acquisition sequence and (iii) a minimum dependence on the dispersion probabilities of the Aerobee vehicle. A preliminary flight reconstruction shows that the chosen nominal was closely achieved, second contact occurring only seconds before rocket apogee.

The operational part of the rocket eclipse programme at Wallops Island was run by NASA, which also furnished the STRAP III pointing control used to orient the payload to the eclipsed Sun. This inertially referenced triaxial pointing control, using rate integrating gyros and assisted by an optical eclipse sensor, successfully manoeuvred and acquired the eclipsing Sun at an early stage of the flight. Throughout data acquisition the maximum pointing excursions in pitch and yaw were ± 10 arc s, with mean body rates of 5 arcs per second. There was a pointing null for the several critical frames taken around second contact with body rates less than 2 arcs per second. As a result, these data are limited only by optical aberrations and film grain.

Alternate exposures of 0·2 and 1 s were taken throughout the sequence of fifty frames, using an absolutely calibrated $f/10$ one metre normal incidence Wadsworth spectrograph. After this sequence of exposures and before re-entry, the camera and payload section were sealed and pressurized to two atmospheres. The payload then made a parachute return within visual distance of the recovery vessel, the aircraft carrier USS Guam. Prompt recovery permitted film development to begin at 23 h 30 m UT. The data are recorded on Kodak 101–01 film and are of excellent quality. The dispersion is 16·6 Å mm^{-1} and the solar images are 4·5 mm in diameter.

A preliminary flight reconstruction shows that the maximum apparent angular rate of the lunar limb at second contact is 0·36 arc s per second. This yields an apparent angular velocity for the Moon of 1·30 arc s per frame.

Second contact occurs close to the twentieth frame in the time sequence, at which point the chromospheric flash spectrum is clearly resolved. The sequence then progresses steadily to a point close to equal mid-totality resulting in spectra entirely dominated by the corona. Several prominences and a plage region are clearly visible in Lyman α and their spectra are isolated and spatially resolved throughout the whole sequence.

Figs. 1*a* and *b* show a part of the total wavelength range between 1100 Å and 1400 Å selected from two of the fifty frames. Fig. 1*a* corresponds to a few seconds after second contact while Fig. 1*b* is much later in the sequence and is close to mid-totality. These two frames illustrate many of the features shown in the complete data. The Lyman α images are of particular interest for one can observe structure and emission out to 1·3 solar radii. This is well beyond the emission from the coronal forbidden lines of FeXII at 1242 Å and 1350 Å, also clearly visible in the figure.

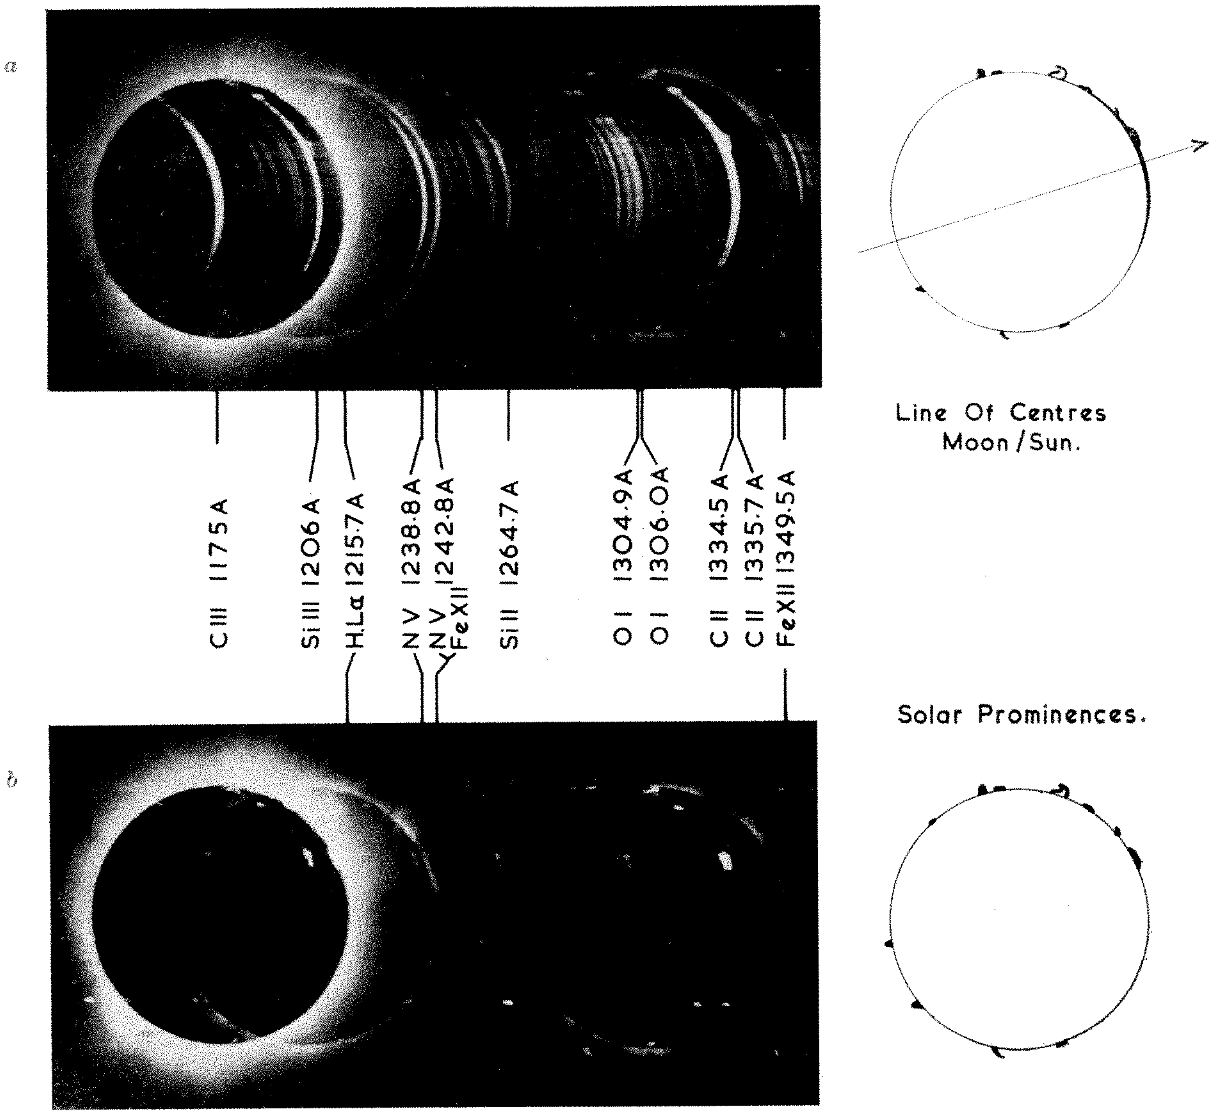

Fig. 1. Flash spectra of the total solar eclipse of March 7, 1970, covering a wavelength region near Lyman α for phases *a* just after second contact and *b* near mid-totality. The wavelength scale and identifications refer to the right-hand side of the lunar limb. Several limb prominences are clearly seen in Lyman α and a key is given in the sketches to the right which have been traced from the originals. The apparent lunar diameter is 72 arc s greater than that of the Sun. Exposure *a* shows a spectrum dominated by the chromosphere near the contact point whereas exposure *b* is mainly a spectrum dominated by the corona. Note the prominence spectra clearly isolated and the extent of Lyman α into the corona. Regions of coronal activity are seen most clearly in the forbidden lines of FeXII. The complete data consist of fifty frames covering a wavelength range 850 Å–2150 Å extending from a phase before second contact to mid-totality.

Preliminary estimates allow radiative recombination, electron excitation and dust scattering (F Corona) to be discarded as possible mechanisms to explain the observed intensity of coronal Lyman α. Thomson scattering can also be eliminated by noting the sharp edge of the lunar disk image, because this mechanism, if present, would result in a Doppler broadening of approximately 30 Å half width. We conclude that the observed intensity is due to resonance scattering of the intense eclipsed Lyman α radiation by residual neutral hydrogen atoms in the corona. Although the relative concentration of neutral hydrogen at a coronal temperature of 2×10^6 K is only about 10^{-7}, the high abundance of hydrogen and the high flux of the Lyman line from lower levels are sufficient to produce the observed intensity within the errors of this early calculation. This "Lα corona" therefore reflects the distribution of neutral hydrogen and has an intensity in the inner corona of the order of 10^{-3} of the low lying chromospheric Lyman α.

We gratefully acknowledge the help of many colleagues in the participating groups. The success of this experiment was made possible by the outstanding contribution of the NASA personnel in the Rocket Sounding Branch of the Goddard Space Flight Center and at the Wallops Island Missile Range. The extensive reduction and analysis of these data are currently under consideration by the participating groups.

Prediction of the Coronal Structure for the Solar Eclipse of March 7, 1970

ON March 3, I made a prediction of the coronal structure of the March 7, 1970, eclipse of the Sun. The model employed is similar to that used for the prediction of the coronal structure at the eclipse of September 22, 1968, and details of the method are described in ref. 1. Observations of this eclipse seem to support[2] the model: "there is a general similarity between the two drawings" (prediction and observation)[3], and a sketch of the observations "agrees well with the prediction; had Schatten drawn his streamers more nearly radial, the agreement would have been almost perfect"[4].

A "source surface" at one solar radius above the photosphere was used in the present prediction, rather than one at 0·6 solar radii as used in the earlier work, to allow for the more active Sun. Comparisons of calculations obtained with this newer value at the end of 1968 agree more closely with observations of Faraday rotation from Pioneer 6 that provided a measurement of the coronal magnetic field (unpublished work of Stelzried *et al.*). Altschuler and Newkirk[5] use a zero-potential surface at 1·5 solar radii above the photosphere for comparisons with the solar eclipse of November 1966. I agree that the method of Altschuler and Newkirk for calculating coronal fields is superior, in principle. I have not had time to incorporate the improvements suggested by these authors into the present work. In practice, however, it is my opinion that uncertainties in the measured photospheric vector magnetic field and in accounting properly for the effects of the coronal plasma outweigh the differences in the two computational techniques. The effects of sunspot magnetic fields, as well as the photospheric magnetic field, were included in this analysis in accordance with Altschuler and Newkirk's work.

Fig. 1 is a prediction made on March 3 of the structure of the March 7, 1970, eclipse of the Sun (total over Mexico, the United States of America and Canada). Solar magnetic observations for this eclipse prediction were terminated on February 26, 1970, due to poor weather conditions in Pasadena, California. A list of the predicted coronal features within 60° of latitude from the solar equator is as follows. They are listed with their position angles (counterclockwise from the north pole) in approximate order of decreasing brightness and certainty: bright features (condensations) at 288° and 95°; streamers from 100° to 120° overlying coronal arches located at 100° and 110°; helmet streamers from 30° to 70° centred on 50° and from 285° to 310° centred on 302°; coronal arches located at 75°, 292° and 278°; broad streamers without arches from 235° to 270° and from 120° to 150°; narrow streamers possibly with greater radial polarization at 235° and at 145°.

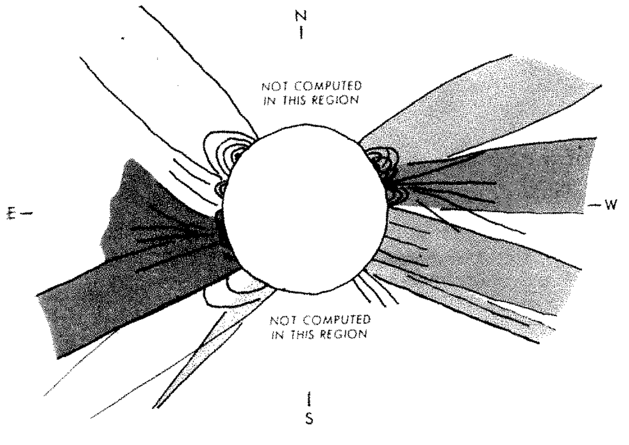

Fig. 1. Eclipse prediction drawn March 3, 1970.

The March 7, 1970, solar eclipse will probably be somewhat brighter and more elliptical in appearance than the September 22, 1968, eclipse (total over Siberia). This results from a greater number of regions of solar activity appearing in the lower latitudes following sunspot maximum.

I thank Dr John M. Wilcox and Dr Robert Howard for their help. This work was supported in part by the US Office of Naval Research, by the US National Aeronautics and Space Administration and by the US National Science Foundation.

Indigenous Lunar Methane and Ethane

RECENT analyses[1,2] of Apollo 11 lunar samples have shown that CH_4 (up to 6 $\mu g\ g^{-1}$) and other gaseous hydrocarbons, ranging from C_2 to C_4, are released on treatment of the fines with aqueous HCl, H_3PO_4 or HF. It was uncertain whether these hydrocarbons were formed by acid hydrolysis or were present as such. We have now shown that methane and ethane arise from both sources.

Samples of Apollo 11 lunar fines (sample 10086·19 bulk fines D) have been examined in two ways; first, by crushing the sample *in vacuo* and examining by mass spectrometry the gases released and, second, by treating the sample with DCl and analysing the isotopic compositions of the methane and ethane. The analytical procedures have been described in detail elsewhere[2,3].

An aliquot of the sample was pulverized by shaking for 16 h in an all-glass ball mill after a vacuum degassing procedure (150° C, 10^{-6} torr, 30 min) to remove adsorbed terrestrial gases. The gases released by crushing included the rare gases (He, Ne and Ar), with Ne and Ar in the lunar isotopic abundances previously measured at the Lunar Receiving Laboratory[4]; CH_4 (1 $\mu g\ g^{-1}$) and C_2H_6 (0·1 $\mu g\ g^{-1}$) were also released (Table 1). A blank experiment conducted with the mill alone revealed only trace quantities of atmospheric gases. In a second experiment, D_2O (99·8 per cent, *c*. 1 ml.) was added to an aliquot of the sample in the ball mill and evaporated under vacuum (150° C, 10^{-6} torr). This procedure was repeated four times in order to exchange, as far as possible, all protonated species (particularly H_2O) with deuterated analogues.

Table 1. HYDROCARBONS AND DEUTERATED HYDROCARBONS RELEASED BY VACUUM CRUSHING AND DCl TREATMENT OF APOLLO 11 FINES

		Quantities of gases released ($\mu g\ g^{-1}$)								
		Methane				Ethane				
Experiment	Sample size (g)	CH_4	CD_4	CD_3H	Other deuterated species	C_2H_6	C_2D_6	C_2D_5H	Other deuterated species	^{36}Ar§
(i) Crushing *in vacuo*†	0·670	1·3	+	+	+	0·12	+	+	+	0·11
(ii) Blank	0	+	+	+	+	+	+	+	+	+
(iii) Crushing *in vacuo* after D exchange	0·540	0·33	0·61	0·26	0·06	0·14	0·14	0·20	0·16	0·09
(iv) Crushing *in vacuo* after D exchange	0·392	0·31	0·72	0·10	0·04	0·25	0·23	0·10	0·15	0·14
(v) DCl on unsieved fines	0·201	1·8	8·4	1·1	+	*	*	*	*	0·54
(vi) DCl on unsieved fines	0·056	1·8	8·6	0·9	+	0·43	0·77	0·23	0·14	0·32
(vii) DCl on fines (30–100 mesh)	0·053	0·89	4·6	0·5	+	*	*	*	*	0·24
(viii) DCl on fines passing 200 mesh	0·054	2·4	11·1	1·5	+	*	*	*	*	0·56

+, Not detectable. * Not measured. † Trace quantities of propane were also observed. § ^{36}Ar is quoted for comparison purposes. This species is known to be trapped in the lunar fines and is virtually absent (0·34 per cent) in terrestrial argon.

Degassed D_2O (15 mg), in a small glass ampoule, was added and pulverized with the sample. The rare gases He, Ne and Ar were again present in their lunar isotopic abundances. Of the methane released, more than 95 per cent could be accounted for as CH_4, CD_4 and CD_3H; 75–80 per cent of the ethane could be accounted for as C_2H_6, C_2D_6 and C_2D_5H (Table 1).

In a third experiment aliquots of the sample were treated (16 h) with DCl (38 per cent in D_2O, isotopic purity 99·5 per cent, 1 ml.). The results of all the DCl experiments are summarized in Table 1. Fifteen per cent of the methane was released as CH_4, almost all (90 per cent) of the remainder being CD_4. Thirty per cent of the ethane was present as C_2H_6 and almost all (90 per cent) of the remainder was C_2D_6 or C_2D_5H. The quantity of methane released in experiments (vii) and (viii) (Table 1) parallels the known total carbon content of size differentiated fines[5].

Our interpretation of these data is that the greater part of the methane and ethane released by crushing or acid treatment of the fines arises from reactions brought about during the experiments. It is likely, as suggested by Ponnamperuma *et al.*, that hydrolysis of carbides, chiefly cohenite (iron, nickel carbide), is the main source of these hydrocarbons, as shown by the evolution of the CD_4, C_2D_6 and almost completely deuterated hydrocarbons. Such hydrolysis can evidently take place during the vacuum crushing process, although prolonged contact (24 h) of the fines with D_2O but without crushing released no hydrocarbons. What is more significant is that most of the remainder of the methane and ethane is completely unlabelled, proving that this fraction must have been present as such in the fines[2,3]. This is emphasized by the fact that DCl treatment of a sample of cohenite of meteoritic origin (courtesy of Dr R. Brett, Manned Spacecraft Center, Houston, Texas) produced methane comprising only CD_4 (95 per cent) and CD_3H (5 per cent).

The carbide in the lunar sample[6,7] is probably of meteoritic origin, but the trapped gaseous hydrocarbons might originally have been present in the igneous lunar rocks (primordial) or could have one or more of the following origins or formations: (i) hydrolysis of carbides *in situ* on the Moon (for example, from hydroxylic groups formed by solar wind implantation[8] of protons); (ii) thermal or radiation induced alteration of indigenous organic matter; (iii) formation from the solar wind, for example by hydrogenation of indigenous or solar wind carbon by hydrogen implanted by the solar wind. Our present data do not distinguish among these possibilities and further experiments are in progress.

We thank SRC, NERC and NASA for financial assistance, and SRC (C. T. P.), NSF (J. M. H.) and PRF–ACS (P. I. A.) for fellowships.

Ball Lightning

Jennison's report[1] of ball lightning inside an airliner reminds me of an observation of my own. It took place on a summer evening in either 1928 or 1929 during a severe electrical storm in the Kootenay Lake Valley, 10 miles from Nelson, BC. The event, in two parts, was seen by a group watching from a sheltered porch and a second (of which I was a member) inside a wooden cottage in a forested area by the lakeside.

Some distance from the shore the first group saw a ball of light drop from the clouds towards our side of the lake. It did not strike the mountainside but came to a stop, floating above the forest. The main road and electrical transmission line along the lakeside were here built parallel to but away from the shore, and led down into a smaller open valley stretching from the lakeside into the mountainside. The ball continued downwards, drifting above the road and the transmission line until it reached the bottom of the valley. Here it drifted to the lake shore and struck one of the piles of a small wharf jutting into the lake. It shattered the pile into long splinters and produced a large detonation.

The indoor group had not been watching the storm. While listening in the living-room to the thunder, we saw a ball of light, similar to Jennison's, emerge from the fireplace and slowly drift across the room. It appeared to pass through a curtained, closed door without making any noise above the rumble of the storm or causing any damage. A loud detonation was heard a few moments after the ball vanished.

We did not know about the first ball until the next morning. At one time the neighbour who had seen it was concerned that it might strike our cottage, but it had carried on to the pile some 200 or 300 feet away. I infer that the first ball, clearly of high energy, induced in some way the formation of the second, low energy ball that emerged from our fireplace.

Jennison's description corresponds to my memory of the indoor ball. It is remarkable that the different surroundings should produce or be accompanied by similar balls: one inside a metal aircraft moving within an electrically disturbed cloud, and the other inside a wooden cottage with a high energy ball moving overhead.

JENNISON'S[1] most unusual ball lightning observation brings several questions to mind: (*a*) Was the ball observed by the crew and other passengers, and if so, what were their reactions ? (*b*) Did the crew in the pilot's cabin report any damage to or unusual behaviour of the electrical equipment ? (*c*) Where and how did the flight of the ball terminate ? (*d*) Was the airplane interior pressurized, and at what approximate altitude was the plane flying ? (*e*) Why did the observer wait more than six years to report on such an interesting phenomenon ?

I would like to add that the antenna feed is a possible access route for the lightning discharge into the airplane.

[1] Jennison, R. C., *Nature*, **224**, 895 (1969).

BALL lightning is a rare phenomenen, which, because of its nature, is virtually impossible to record objectively. Carefully documented reports such as the one by Jennison[1] are therefore valuable.

A similar incident occurred in the Meteorological Office, Boscombe Down, Wiltshire, in the northern summer of 1938. There was a vivid flash with simultaneous thunder. It was assumed that the Dines pressure-tube anemometer, which passed through the roof and was supported by four heavy steel supports embedded in the floor, was struck.

Immediately after the lightning flash, a brilliant white sphere, with a diameter of about 20 cm and diffuse edges, was observed hovering near the anemometer supports. The diameter, symmetry and absence of structure agree with Jennison's description. No heat radiation was noted. The motion differed from Jennison's case. The object followed an irregular course; it travelled from one anemometer leg to the other, and then from the anemometer to a radio receiver/transmitter which was being operated at the time. The distance from the anemometer to the radio set would be about 2 m, and the height above the floor about 1·5 m. The object disappeared as it reached the radio set, perhaps 3–5 s after its appearance.

The radio operator witnessed the incident and generally agreed with the motion and other properties already described.

Although this report is thirty years old, it is believed to be reliable.

It is possible that such occurrences are attributable to physiological or psychological origin; the close agreement between different observers would not necessarily detract from this suggestion. Alternatively, photographs, claimed to be of ball lightning, have appeared in the popular press. Whatever the cause, it seems desirable to place the observation on record.

Late Quaternary Chronology of the Nakuru–Elmenteita Basin, Kenya

IN 1967[1] I gave details of a shoreline of a former lake in the Nakuru–Elmenteita basin of Kenya at an altitude of about 6,370 feet above sea level, or about 600 feet above the present surface of Lake Nakuru. It was suggested then that, although this shoreline might still qualify to be called "Gamblian" after the formerly accepted nomenclature for the late Quaternary in East Africa[2], it is necessary to be extremely cautious in using this nomenclature, because its usage involves assumptions of dating and correlation which are not borne out by the results of recent fieldwork.

Some further evidence from the Nakuru–Elmenteita basin has been obtained in the form of a radiocarbon date for material which seems to have close links with the 600 foot shoreline. The dated sample consists of the shells of Mollusca which were found *in situ* in a matrix of pale buff diatomaceous silt. The exposure is at an altitude of 6,188–6,192 feet above sea level, or more than 400 feet above the present surface of Lake Nakuru. The material is clearly of lacustrine origin, both from the character of the silt, and from the species of Mollusca which have been identified in it.

The shells have been dated by Dr D. Thurber of Lamont Geological Observatory. The age obtained for the shells using the 5,585 half-life for radiocarbon and assuming the initial $^{14}C/^{12}C$ ratio to be atmospheric was 9,650 ± 250 years before 1950 (L–1201). Dr Thurber also analysed the $^{14}C/^{12}C$ ratio in samples of water from Lakes Nakuru and Elmenteita and has informed me that no adjustment to the above date need be made on the basis of these analyses.

Dr B. W. Sparks of the Cambridge University Department of Geography has kindly studied another sample of the shells and lists the following species: *Corbicula africana* (Krauss) (most common); *Melanoides tuberculata* (Müller) (second in abundance); and very small numbers of *Pisidium* sp., *Burnupia* sp., *Bulinus* sp., *Anisus natalensis* (Krauss) and *Biomphalaria* sp. These are all freshwater species and there were no land snails in the samples. Sparks suggested that these snails, in particular *Corbicula* and *Melanoides*, are indicative of a lake of appreciable size rather than of a small perennial or temporary body of water. It is not possible from this sample to obtain a precise indication of the depth of water or length of time implied by the deposit.

The only other record of Mollusca from the Nakuru–Elmenteita basin is that by Leakey[2]; he described shells from various localities, including Gamble's Cave. The Gamble's Cave shells included the following species: *Lymnaea elmenteitensis* ?Smith, (rare); *Bulinus* sp. (fragments); *Melanoides tuberculata* (Müll.) (very abundant); and *Corbicula africana* (Krs.). The list of Mollusca was prepared by M. Connolly and is given in Appendix D of Leakey's book[2]. The shells are described as being obtained "from the beach gravel at 510 feet above present lake level in Gamble's Cave II".

There seem to be no more recent reports of Mollusca from this basin, and I was only able to find one occurrence of shells in the diatomaceous silts. The silts containing the Mollusca at this locality are similar in appearance to many of the other outcrops of diatomaceous material which occur all over the basin. These deposits are found up to an altitude of about 6,330 feet, and many of them seem to represent sedimentation in fairly calm water below the 600-foot shoreline. It is not possible to state definitely that the silts that contain the Mollusca, which have been shown to be about 9,650 years old, are exactly contemporaneous with the 600-foot shoreline. Their relationship to certain nearby lake features, however, suggests a possible broad correlation. The Mollusca-bearing silts outcrop in a small gully on the north-east slope of the volcano Karterit (just below the "a" of the word Karterit on the map, Fig. 1 of my earlier paper[1]). Upslope from this gully are a number of other probable lake features; silts, pebble-bands, surface pebbles, and finally a possible shoreline cliff, the Karterit notch. This is an overhanging cliff, about 6 feet high, cut in the rocky slope of the volcano. It runs across the slope for several hundred yards and when conditions of light and vegetation are suitable it is clearly visible from the main Nairobi–Nakuru road. The identification of this feature as a lake shoreline is not absolutely definite; however, it does not seem to have been formed by faulting of the cone, and its altitude correlates well with that of the best preserved remnant of the 600-foot shoreline, the Menengai shoreline cliff, about 23 miles away at the north end of the Nakuru–Elmenteita basin. The altitudes are:

Base of Karterit notch:	*circa* 6,365 feet
Base of Menengai cliff:	*circa* 6,370 feet

Even if the Mollusca-bearing silts cannot definitely be linked with the 600-foot shoreline, they were clearly laid down when the lake level was over 400 feet higher than it is now. There is no evidence of a prolonged pause in the fluctuations of the lake level at any altitude between the approximately 600-foot and 400-foot levels (6,370–6,190 feet); the date of the 600-foot shoreline itself may thus be quite close to the date of the silts which lie about 180 feet below it.

Further evidence, which to some extent supports my results, has been obtained from an archaeological excavation carried out by Miss Barbara Anthony of Harvard University at Prospect Farm, which is also in the Nakuru–Elmenteita catchment area. At Prospect Farm, in an excavation well above the highest former shoreline, Miss Anthony obtained some charcoal from a horizon containing an industry known as Kenya Capsian. This charcoal was dated by Geochron Laboratory and gave a date of 10,560 ± 1,650 BP (GX–224). A Kenya Capsian industry has also been described[2] as immediately overlying the beach sand with Mollusca at Gamble's Cave. This beach sand is at an altitude of 6,344 feet and seems to be a lake sediment laid down close below the 600 foot shoreline[1]. Prospect Farm is about 7 miles from Gamble's Cave and the Prospect Farm date for the Kenya Capsian industry in the Nakuru–Elmenteita basin thus provides an indication that the Gamble's Cave beach sand may be in the vicinity of 9–11,000 years old. Further evidence of the relatively late date of the Capsian industry is provided by the bone harpoon found at Gamble's Cave and described by Oakley[3], and by numerous north African radiocarbon dates for Capsian industries.

The evidence suggests therefore that there were very high lakes in the Nakuru–Elmenteita basin as recently as 10,000 years ago. As yet, there is not sufficient information for a detailed chronology of lake level fluctuations in the basin. The evidence from this basin shows a general agreement with the sequence suggested by Richardson from his study of a core from the bed of Lake Naivasha[4]. It is hoped that further investigations in these areas will provide more information and enable firm links to be made. Until such correlations can be established between adjacent areas, which at present experience basically similar climatic conditions, it is unwise to put too much faith in wider correlations between areas of very different present day climates.

The "Keuper" Series of the British Trias in the Northern Irish Sea and Neighbouring Areas

Considerable interest in the geology of the Irish Sea has followed from the exploration of the area for hydrocarbon deposits. We present here a brief account of the results of palynological studies of the "Keuper" Series which have been carried out at the Institute of Geological Sciences, Leeds.

The palynological examination of material from the Institute of Geological Sciences (IGS) boreholes in Cheshire, the Irish Sea and Northern Ireland, and from Imperial Chemical Industries Ltd boreholes in Cheshire, has yielded information relevant to the study of the northern part of the Irish Sea.

In Cheshire the "Keuper" sequence (shown diagrammatically in Fig. 1) has yielded miospore assemblages which give the age data shown in Table 1.

Table 1. AGE OF CHESHIRE "KEUPER" SEQUENCE

Location	Borehole	Age
360 feet above base of the Middle "Keuper" Marl	Wilkesley Borehole (IGS)	Ladinian
Basal part of Middle "Keuper" Marl	Wardle Borehole (IGS)	Ladinian
2 feet above base of the Middle "Keuper" Marl	Holford (ICI) borehole	Anisian
Approx. 80 feet above the base of the "Lower" "Keuper" Saliferous beds	Holford (ICI) borehole	Anisian
122 feet below the top of the Lower "Keuper" Marl	Wilkesley Borehole (IGS)	?Anisian
58 feet above the base of the Lower "Keuper" Marl	Wilkesley Borehole (IGS)	Upper Scythian —Anisian
Waterstones	Houndslough Borehole (IGS)	Upper Scythian
"Keuper" Sandstone[1]	Alderley Edge (outcrop)	Upper Scythian

In the Irish Sea, a core of "Keuper" Marl facies from the IGS Continental Shelf Unit 69/2 Borehole, situated 53° 40′ 30″ N, 04° 03′ 09″ W, about 37 miles west of the mouth of the River Ribble[2], has yielded miospores suggestive of an upper Scythian age.

In Northern Ireland, the IGS Langford Lodge Borehole on the eastern side of Lough Neagh proved to have a "Keuper" sequence which consisted entirely of "Keuper" Marl facies. Miospore assemblages from this section have shown that the "Keuper" Marl includes deposits, ranging in age from upper Scythian at the base to ?Norian at the top[3]. The lower part of the Langford Lodge sequence is therefore the time correlative of entirely different facies, the "Keuper" Sandstone and Waterstones, in Cheshire (see Fig. 1). It seems therefore that the "Keuper" sequence in the northern Irish Sea area could consist largely of "Keuper" Marl facies, an interpretation which is supported by evidence from the Continental Shelf Unit borehole.

The Lower (Anisian) Saliferous Beds of Cheshire are overlain by argillaceous deposits (the Middle "Keuper"

Marl) which are now known to be partly of Ladinian age, and which are succeeded by the upper saliferous beds for which no direct evidence of age is available. In view of the age of the Middle "Keuper" Marl, however, and the fact that a similar thick halite has yielded Carnian miospores[1], the upper halite in Cheshire may be of Carnian age. It is significant that the halite units are restricted to the "Keuper" Marl facies, which is thought to have accumulated in a hypersaline environment. The presence of microplankton (*Micrhystridium*, *Veryhachium* and *Tasmanites*) in palynological residues from the Lower and Middle "Keuper" Marls of Cheshire and the basal "Keuper" Marl at Maer, Staffordshire, indicates that the water in which these deposits accumulated was derived from a marine source.

The Waterstones and "Keuper" Sandstone which underlie the "Keuper" Marl in Cheshire and much of the Central Midlands represent, respectively, the deposits of a littoral or estuarine marine or semi-marine and a fresh-water fluvial deltaic environment[1]. Palynological data from Worcestershire[1,4], which was up-river from Cheshire during the deposition of the "Keuper" Sandstone but into which the hypersaline environment gradually transgressed during the later Trias[1], indicate that the "Keuper" Sandstone and Waterstones of Worcestershire are the time-correlatives of the "Keuper" Sandstone, Waterstones, Lower "Keuper" Marl, Lower Saliferous Beds and probably part of the Middle "Keuper" Marl of Cheshire (Fig. 1). A knowledge of the distribution and the ages of the main "Keuper" facies in different areas makes it possible to suggest where halite may have formed at a particular time. It is clear, for example, that a halite representative of the Lower Saliferous Beds of Cheshire will not be found in Worcestershire because, during the Anisian, that area was occupied by a freshwater fluvial environment. Later, however, a hypersaline environment pervaded both Cheshire and the Central Midlands, and an important halite of proved or probable Carnian age is found in Cheshire (the Upper Saliferous Beds), and in Staffordshire and Worcestershire. It therefore seems that halites of approximately the same age as the Anisian and Carnian halites of the North Sea Basin[5,6] occur in the Midlands where a "Keuper" Marl facies of the appropriate age occurs. The Cheshire Basin sequence may also include an upper Scythian halite because traces of halite occur within the basal 350 feet of the Lower "Keuper" Marl[7]. Similar reasoning, applied to the situation in the northern Irish Sea and Northern Ireland where the "Keuper" Marl facies includes deposits of upper Scythian age, suggests that three halites corresponding to the upper Scythian, Anisian and Carnian halites of the North Sea Basin may also occur there (Fig. 1).

The existence of halite deposits in the "Keuper" Marl of the Isle of Man[8], Walney Island (Furness)[9] and at Preesall in west Lancashire[10] has been known for some time. In view of the proximity of the Isle of Man halite and the lower of the two Walney Island halites to the base of the "Keuper" Marl facies, it is possible that these may be of upper Scythian age. In the absence of material from the evaporites at these localities, however, their age must remain conjectural. Work currently being carried out by the IGS in west Lancashire is planned to elucidate the halite sequence in that area. In Northern Ireland, the Langford Lodge Borehole, on which palynological work has been carried out, was chipped and there is no record of the existence of any halite deposits in that section. In the IGS Larne Borehole[11], however, on which palynological work remains to be done, a section of over 3,000 feet (923 m) of "Keuper" Marl facies included three distinct halite units. These halites may prove to be

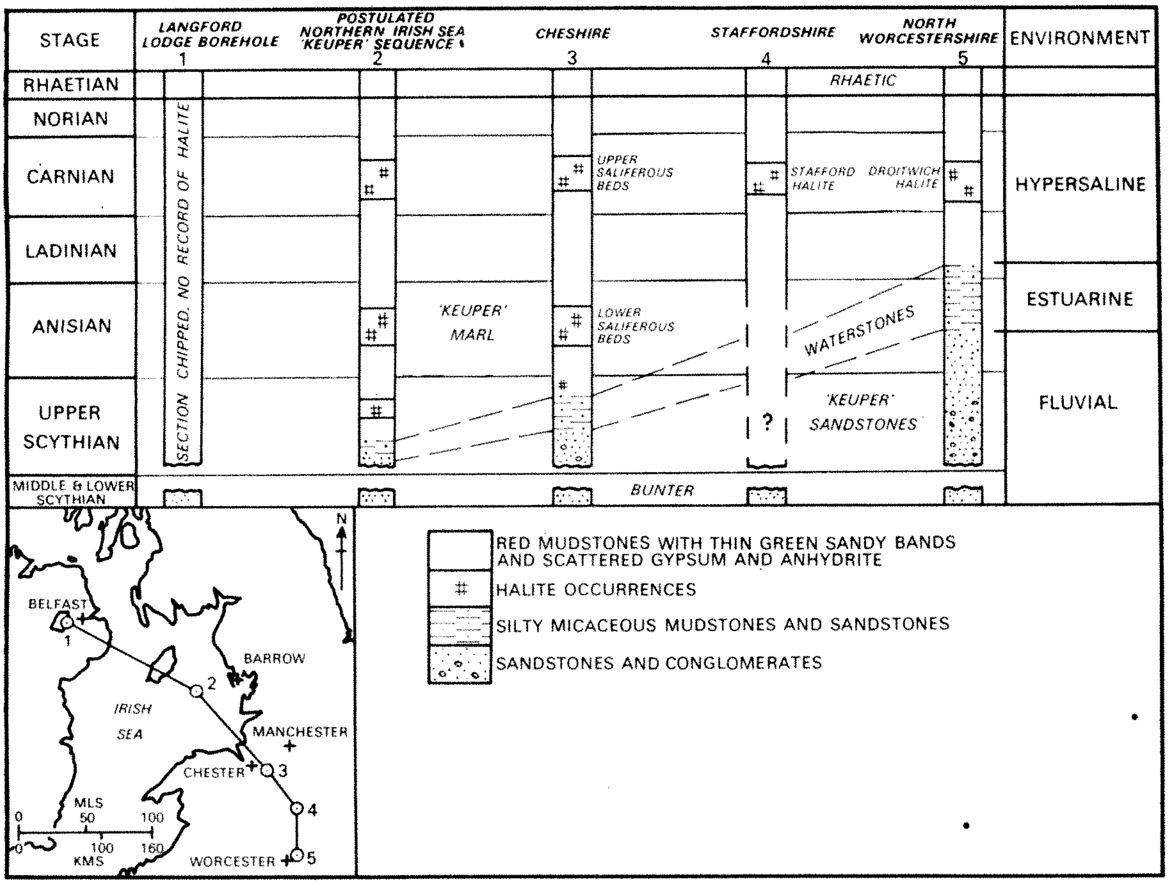

Fig. 1. The time-facies relationships (diagrammatic) in the "Keuper" series of the West Midlands, Cheshire and the northern Irish Sea area.

correlatives of the major halite units of the North Sea sequence.

Transform Faulting along the De Geer Line

DE GEER[1] in 1926 first referred to the existence of a physiographic lineament following the western continental slope of the Barents Shelf from Norway to Svalbard, then running along the north-eastern continental slope of Greenland and Canada. Subsequent authors[2,3] suggested that extensive dextral strike slip movements had occurred along this line during the continental drift of Greenland and North America away from Eurasia.

Harland[4] has noted that the implied reconstruction is consistent with similarities between the Mesozoic and Tertiary stratigraphy in Spitsbergen and the Canadian Arctic.

Conversely, sinistral transcurrent faulting has been postulated[5] along the line of the East Greenland and North Eurasian continental margins. This hypothesis is refuted by the evidence presented here and by the distribution of seismicity[6,7] and magnetic anomalies[8] in the Arctic Ocean.

Recent bathymetric surveys have revealed the general morphology of the Norwegian and Greenland Seas[7,8] and of the Arctic Ocean[9] (Fig. 1). The seismic activity in the area is largely restricted to a linear zone, part of which runs along the Spitsbergen Fracture Zone[7], parallel to the De Geer Line.

Four earthquakes along the Spitsbergen Fracture Zone, occurring since the establishment in 1962 of the USCGS World Wide Standardized Seismograph Network, have had body wave magnitudes greater than 5·0. These are listed in Table 1.

A study of the first arrivals of P waves from these resulted in focal mechanism solutions for events 2 and 3 (Fig. 2). Solutions were not obtained for events 1 and 4, whose seismograms were unreadable because of a gradual onset (event 1) and a high noise level following a large event elsewhere (event 4). The focal mechanisms of events 2 and 3 both indicate two steeply dipping, orthogonal nodal planes which strike about 310° and 40°. Of each pair, that striking about north-west was chosen as the fault plane, for the following reasons: (1) the line of earthquake epicentres follows a north-west trend; (2) this trend is closely parallel to the bathymetric feature of the Spitsbergen Fracture Zone; (3) continental structures of Mesozoic and Caenozoic age in Spitsbergen show similar trends. The Spitsbergen Fracture Zone is thus confirmed to be an active transform fault[12] with dextral strike slip motion, separating the spreading axis of the Arctic Ocean from that of the North Greenland Sea.

Table 1. FOUR EARTHQUAKES ALONG THE SPITSBERGEN FRACTURE ZONE

Event No. (this paper)	USCGS event No.	Date	Origin time GMT	Epicentre Lat.	Epicentre Long.	Body wave magnitude
1	4,439	Nov. 27, 1966	20–13–1·5	78·50 N	6·40 E	5·6
2	3,962	Oct. 18, 1967	1–11–44·8	79·80 N	2·40 E	5·7
3	4,415	Nov. 23, 1967	13–42–1·6	80·20 N	1·00 W	5·8
4	1,256	Apr. 7, 1968	5–16–24·9	81·50 N	3·90 W	5·3

According to the theory of plate tectonics[13], it is possible with the present and other data[7,14] to determine the pole of rotation of Greenland and North America with respect to Europe. Great circles were drawn through the epicentres perpendicular to the slip vector for the strike slip displacement events on the Spitsbergen Fracture Zone, and north of Iceland[7], and for a normal displacement event in the Laptev Sea[7]. These great circles for the three strike slip faults are all very close together, and intersections between them lack control along their arcs. The normal faulting solution from the Laptev Sea does give some control, however, although it must be assumed that of the two nodal planes obtained by Sykes, that striking N 338° E is the fault plane. The intersections thus obtained are shown by closed circles in Fig. 3. They have a mean position of 124° E ± 5°, 66° N ± 5°. The angular velocity of the rotation about this pole, based on magnetic data from the Reykjanes Ridge[13], is $3 \cdot 7 \times 10^{-7}$ degrees yr^{-1}.

This may be the best position of the instantaneous rotation pole of Greenland and N. America, with respect to Europe, that can be determined with the data now available, but it is emphasized that further data should yield a more accurate position. It is perhaps worth noting that this pole seems to be further south-east than the poles obtained by Bullard, Everett and Smith[15] and Le Pichon[16], probably because these poles pertain to the total movements of the two plates, rather than to the (geologically) instantaneous pole.

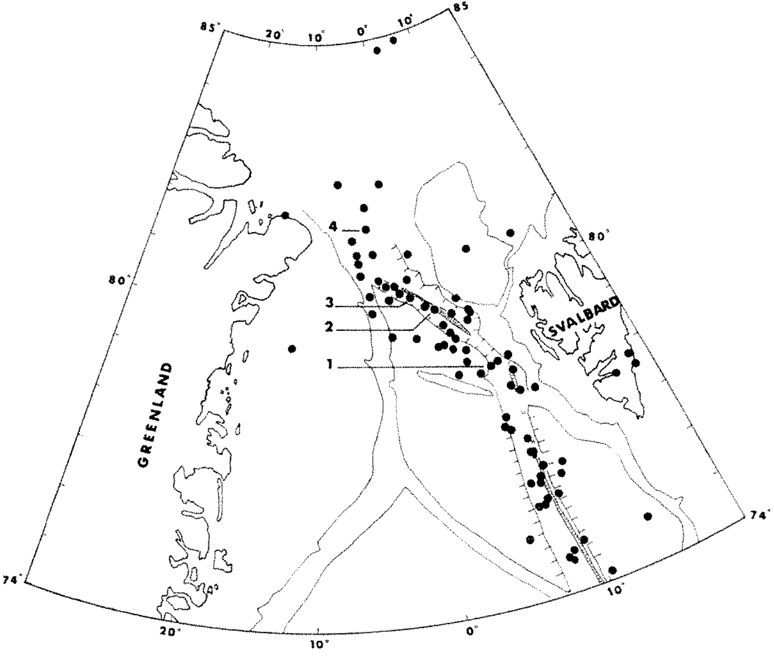

Fig. 1. Outline of bathymetry of the Norwegian–Greenland Sea between Greenland and Svalbard, after Johnson and Eckhoff[9]. Solid circles are earthquake epicentres after Sykes[7], and subsequent USCGS lists. Numbers indicate locations of events listed in Table 1, which lie along the Spitsbergen Fracture Zone.

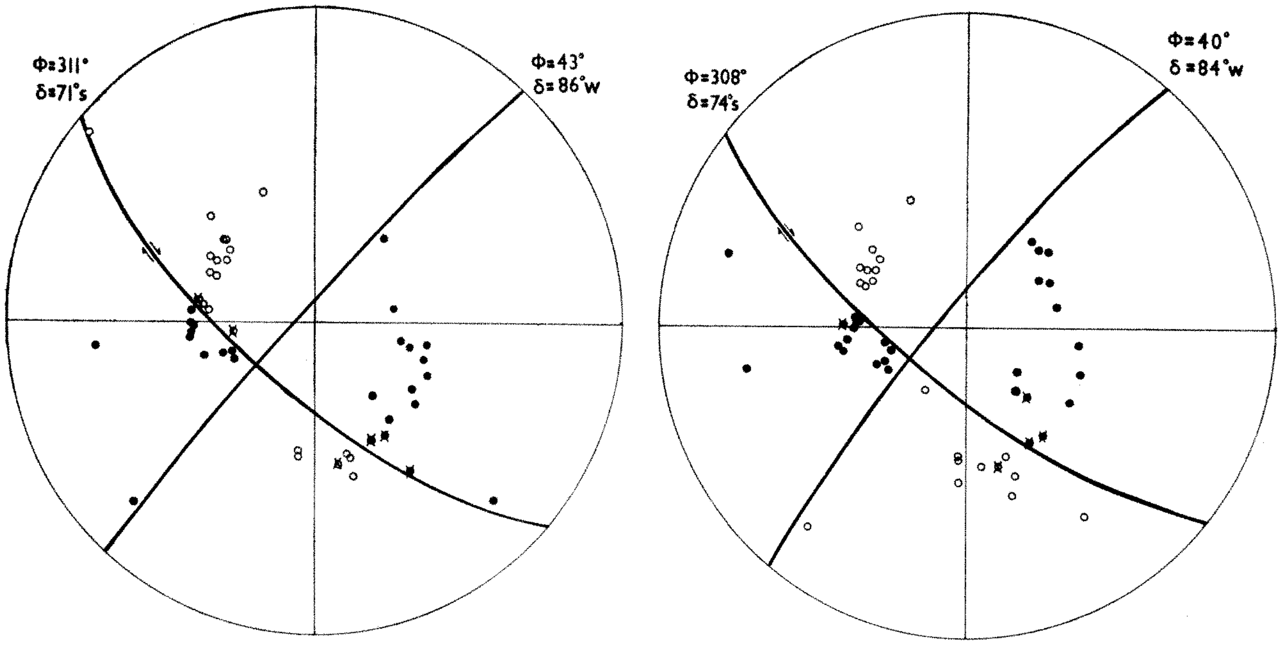

Oct. 18, 1967

Nov. 23, 1967

Fig. 2. Focal mechanism solutions for events 2 and 3 on the Spitsbergen Fracture Zone. Equal area projection of the lower hemisphere of the radiation field. Solid circles indicate compressional first arrivals, open circles dilatational ones. Crosses mark stations near nodal planes. Arrows indicate sense of displacement on plane chosen as the fault plane.

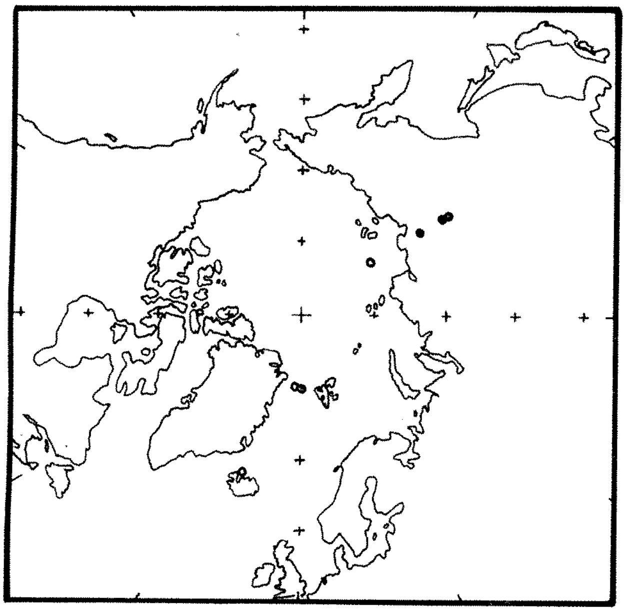

Fig. 3. Equal area projection of northern continents. Open circles mark location of epicentres used to determine instantaneous rotation pole of European plate relative to N. America–Greenland plate. Solid circles are intersections of normals to slip vectors—see text.

Orientation of 3-D Graphite in Carbon Fibres

CARBON fibres have been produced that have high strength and stiffness and a polycrystalline structure consisting of carbon crystallites oriented in the direction of the fibre axis[1,2]. Some evidence for recrystallization has been reported for carbon fibres heat treated in a nickel matrix[3,4] and in boron[5]. Here we consider the effect of recrystallization on the preferred orientation of carbon fibres during an improvement in order of the carbon atoms.

As part of a cooperative programme directed towards an understanding of the fundamental structure of carbon fibres, heat treatments have been performed (at the Weapons Research Establishment, Adelaide) over the temperature range 1,600°–3,000° C for periods of 10–20 min, using a dynamic atmosphere of argon and a carbon block container. A heterogeneous surface deposit was produced in suitable conditions during heat treatment as a result of impurities contained in the carbon block. Regions of the fibres on which the surface deposit occurred could be separated magnetically from clean regions and the contamination studied directly.

Fig. 1 is a scanning electron micrograph of a bundle of fibres, and shows the typically globular nature of the deposit. X-ray analysis shows that the surface deposit is a ^{14}Fe per cent Si solid solution, and is supported by spectrographic analysis. Estimates of the effective size and orientation of carbon crystallites in regions selected by direct observation were then made by X-ray diffraction and electron microscopy.

The degree of preferred orientation of the carbon crystallites aligned along the fibre axis was estimated from a measure of the half widths of the (002) diffraction arc. The effective size of the crystallites normal and parallel to the basal planes was estimated from the line broadening of the (002) and (100) diffraction arcs respectively.

The effect of surface contamination on the graphitization of a carbon fibre at 2,500° C is shown in Fig. 2. The X-ray pattern (Fig. 2*a*) of a clean area is typical of high-modulus carbon fibre[6] with the basal planes highly oriented along the fibre axis and a crystallite size of approximately 50 Å in both the *a* and *c* directions. Fig. 2*b* is typical of fibres with fine surface deposits—the (101) reflexion indicates the presence of three-dimensional-ordered (3-D) graphite which has a measured interlayer spacing of 3·35 Å. The average crystallite size of the 3-D graphite is too large to be measured by line broadening. The marked change in the (002) diffraction line from arcs to a uniform ring illustrates the reduction in basal plane alignment along the fibre axis. This change is considerable, for Fig. 2*a* shows (002) arcs with a distribution half width of 30°, whereas in Fig. 2*b* the full ring is present with arcs of half width 54° superimposed.

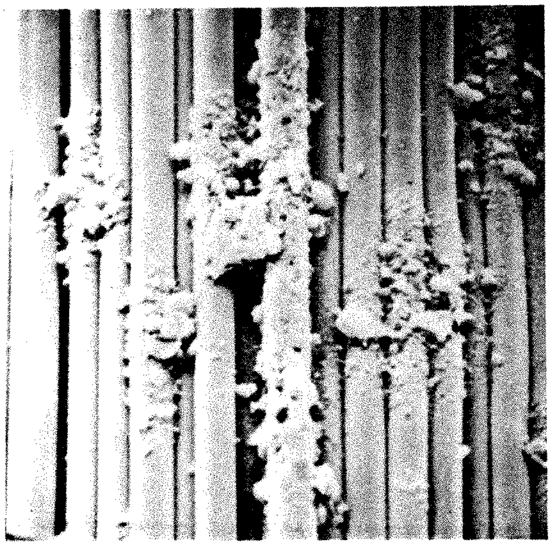

Fig. 1. Scanning electron micrograph showing Fe-14 per cent Si surface deposits on carbon fibre heat treated to 2,500° C (by courtesy of V. Silva, Defence Standards Laboratories, Melbourne).

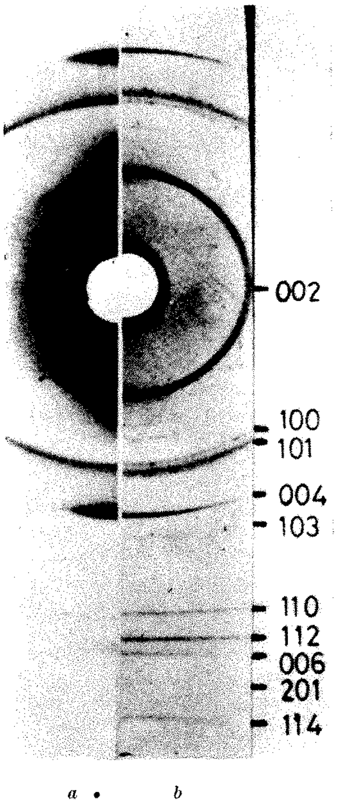

Fig. 2. X-ray transmission pattern of carbon fibre heat treated to 2,500° C. *a*, Area free from surface deposit, showing normal preferred orientation; *b*, result of surface deposit showing 3-D order and reduced preferred orientation.

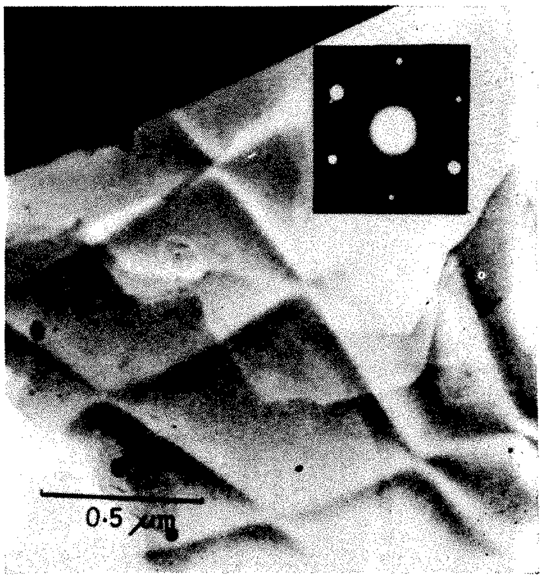

Fig. 3. Electron microscope picture of single crystal graphite in contaminated carbon fibre. The network of dislocations shows contracted nodes.

Using a flame polishing technique, selected areas of the fibre similar to those corresponding to Fig. 2*b* were examined in the electron microscope. Fig. 3 confirms the presence of 3-D graphite, and shows a network of basal dislocations identical to that observed in single crystal graphite. Graphite platelets are observed in these regions in completely random orientation, bearing little relation to the original microstructure.

Preliminary mechanical tests suggest that lengths coated with the surface deposit have lower fracture strengths than clean fibre lengths. This implies that the presence of single crystal graphite platelets oriented perpendicular to the fibre axis may be important in reducing the fracture stress of commercially produced high-modulus fibres[2].

The role of the ^{14}Fe per cent Si deposit in catalysing the growth of three-dimensional graphite platelets is similar to the formation of graphite Kish crystals on the surface of Fe-Si casting melts[7]. The nucleation conditions, the tendency towards a random growth of the graphite platelets, and the effect on fibre fracture stress are being further investigated.

Flow at the Junction of Two Pipes: the Shape of the Separation Surface

THE subject of flow in branched pipes is largely unexplored. Some work has been carried out by Bugliarello and Hsiao[1,2] and others (see ref. 3, and references therein), principally with an eye to applications in the microcirculatory system. The problem of "what fluid goes where" is particularly vital in the case where the destination of suspended particles is in question. This is naturally one of the major questions of circulatory physiology.

To provide a basis for the study of flow at a junction of two pipes, we have studied several particularly simple cases. We have avoided the sharp-edged junctions of Bugliarello and Hsiao[1,2], for we agree with the criticism of these expressed by Neumaster and Krovetz[3]. Moreover, in order to elucidate basic phenomena we have worked entirely with a Newtonian fluid (water)—previous studies have used blood. The basic situation is as follows.

A cylindrical pipe of diameter d ("the branch") leads off from the side of another of diameter D ("the tube"), where $d < D$. Fluid is forced under pressure down the tube; some is drawn off from the branch, and the rest will continue down the tube. A surface may be envisaged dividing these two portions of fluid. This, following Bugliarello and Hsiao[1], we term the "separation surface". We report here on a series of experiments to determine the shape of this surface far upstream from the junction. Our experiments cover only the case where the two pipes meet at right angles. We believe this to be the first experimental determination of a separation surface.

In our apparatus, water flowed under gravity down a 161·0 cm length of 4·76 cm diameter (internal) brass tubing, which was fitted flush into a bored 'Perspex' block of matching internal diameter. Replaceable sections of this block allowed for varying ratios d/D to be investigated. The values we chose were: 0·053, 0·106, 0·159, 0·212. The edges of the junction were bevelled to eliminate sharp corners.

Below the junction the water flowed through peristaltic pumps fitted to both tube and branch. Each pump was stabilized with a Helmholtz resonator so that the resulting flow was steady to within 8 per cent in the branch and 3 per cent in the tube. The water was then returned to the top of the tube.

According to Schlichting's inlet length theory[4], the length of tube made feasible Reynolds numbers (Re) of up to 200 without losing fully developed Poiseuille flow. We were able to achieve Reynolds numbers as low as 30 before the times involved in the experiment became impracticably great. This covers a range of biologically applicable Reynolds numbers but leaves some of the area relevant to the microcirculation unexplored. It will be noted, however, that the results seem to be largely independent of Reynolds number.

The ratio β between the volume rates at which fluid was extracted from the branch and from the tube could also be varied. We did not, however, investigate flow profiles other than parabolic, although it would be of interest to see if the results described here apply also to plug flows.

The flow was made visible by the almost neutrally buoyant dye "Edicol Supra" Blue VRS, leaked in through a hypodermic syringe 3·55 cm upstream from the junction. The syringe could be moved backwards and forwards with complete freedom by means of a micrometer screw. There were nine small holes drilled into the 'Perspex', just large enough to admit the syringe. Those not in use were blocked up with small plugs. One of these holes was drilled along a diameter of the tube on the side directly opposite the branch and parallel with the branch. The other eight were parallel to the first and evenly spaced across half the diameter of the tube on the side opposite the branch. The shape found for the separation surface was completed by symmetry.

Readings were made by moving the syringe in from outside the separation surface, through the surface and back again. Three sets of readings were taken. The position of the dye stream we used was that at which the dye divided equally between branch and tube.

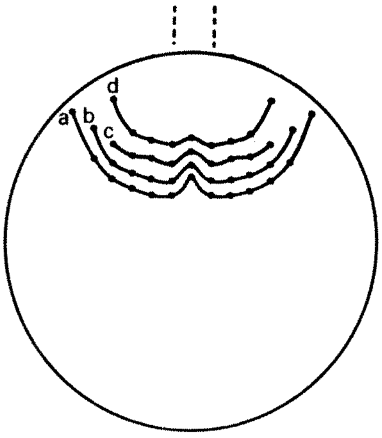

Fig. 1

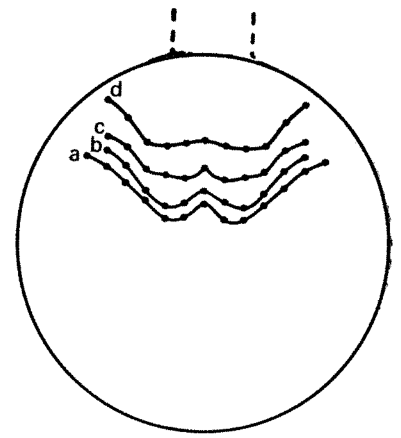

Fig. 2

Fig. 1. Separation surfaces for Re = 123·7, $d/D = 0{\cdot}106$, $\beta = 0{\cdot}107$ (*a*), 0·083 (*b*), 0·061 (*c*), 0·041 (*d*).

Fig. 2. Separation surfaces for Re = 123·7, $d/D = 0{\cdot}212$, $\beta = 0{\cdot}107$ (*a*), 0·083 (*b*), 0·061 (*c*), 0·041 (*d*)

The results are shown in Figs. 1 and 2. No points are shown close to the walls because flow was so slow here that repeatable results could not be obtained. The two cases Re = 123·7; $d/D = 0{\cdot}106$, 0·212 are shown in Figs. 1 and 2 respectively for values of $\beta = 0{\cdot}041$, 0·061, 0·083, 0·107. Also investigated were $d/D = 0{\cdot}053$, 0·159.

Within the stipulated range of values for Re (30 to 200) and for constant β, d/D, no change in the separation surface could be detected. When d/D is increased for constant Re, β, however, more fluid is extracted from regions near to the wall; the profile thus appears flattened and is situated nearer to the branch wall (compare Figs. 1 and 2).

It will be noticed that the shape found for the separation surface far upstream is similar to one of the various shapes postulated by Bugliarello and Hsiao[2], except that the non-repeatability of results near the wall means that we cannot consistently define a separation surface in this area and expect the result to be meaningful in practice. The prime cause of the non-repeatability was the residual unsteadiness of flow in both tube and branch.

Work is proceeding on the theoretical modelling of the phenomenon. Any successful account will have to explain in particular the marked dip in the curves close to the line of symmetry and the constancy of this feature over a wide range of experimental conditions.

We thank Professor B. R. Morton for helpful discussions and for letting us use the Geophysical Fluid Dynamics Laboratory of Monash University. Mr T. Long built the apparatus and gave technical help. D. C. B. was supported by a Monash graduate scholarship.

BIOLOGICAL SCIENCES

Re-examination of a Supposed Case of Specific Cell Adhesion

SPECIFIC adhesion of sponge cells, such that only the cells of a single species will adhere together, has been claimed by many workers[1-3]. Indeed, the particular specific behaviour which has been reported[3] for mixtures of cells from pairs taken from *Haliclona occulata*, *Halichondria panicea*, *Microciona prolifera* and *Clione celata* has been regarded as one of the most remarkable examples of specific adhesion or cell recognition. Sara[4-6] has tested combinations of other species of marine sponge for specific adhesion without success. In all work on sponge cell aggregation, the recognition of the species type of the cells in the aggregates has depended on subjective observation of the colour of the aggregate. I find this criterion defective, for it is extremely easy to fail to observe a small proportion of cells of one colour and species type scattered in a mass of cells of a different colour and species type. Furthermore, only a proportion of the cells of highly coloured sponges may carry the pigment distinctive of a species, so that it is uncertain what happens to the unpigmented cells.

Another difficulty lies in the possibility that the claimed separation of cells in a mixture of two species types is the result of the aggregation of one species type preceding that of the other, so that aggregates tend to contain cells of one species type alone—a form of behaviour which gives the same result as specific adhesion. I have recently introduced an experimental test for specific adhesion, which does not require the identification of the species type of the cells[7]. It depends on the measurement of the collision efficiency of aggregating cells in a suspension culture. Collisions are produced by stirring or shaking the suspension. The collision efficiency is the probability that two cells, or a cell and an aggregate, or two aggregates adhere on collision. The collision efficiency (stability ratio) is a function of the adhesiveness of the cells: the greater the probability of adhesion, the greater the adhesiveness. (The relationship has been treated in detail in ref. 8.) The basis of the technique can perhaps be best appreciated from an example. Suppose first that two different cell types are of identical adhesiveness and thus collision efficiency, and are non-specific in their adhesion. The adhesiveness and collision efficiency of any mixture of the two cell types will be the same as that for either type alone. But if there is specificity of adhesion, then—because collisions take place between cells of unlike type which will be totally ineffective in producing adhesions—the measured collision efficiency is smaller than that for either cell type alone. The expected collision efficiency in the case of a mixture of two types of cell, in proportions n_1 and n_2, is $\alpha_1 n_1 + \alpha_2 n_2$ for non-specificity of adhesion and $\alpha_1 n_1^2 + \alpha_2 n_2^2$ for specific adhesion, where α_1 and α_2 are the collision efficiencies of cell types 1 and 2. (The full theory is given in ref. 9.) The collision efficiency of cell suspensions is measured by aggregating the suspensions under a known shear rate in a Couette viscometer and determining the total particle concentration at various intervals by haemocytometry or Coulter counting[10]. Application of the treatment of particle collisions in a laminar shear flow according to Swift and Friedlander[11] allows calculation of the collision efficiency. Because this technique avoids the problems of identification of individual cells inherent in other methods and allows a quantitative measure of any specificity that may be found, I feel that it is appropriate for the re-examination of the nature of the adhesiveness in the sponges Humphreys used.

Because *Microciona prolifera* seems to be unavailable in the United Kingdom, these experiments were confined to *Haliclona occulata* and *Halichondria panicea*. Sponges were collected live at Linne Mhurich, Argyll (National Grid reference NR 724827), and dispersed into cell suspensions using the calcium chelating agent EDTA[7]. This technique is similar to that used by Humphreys, the main difference being that the cells are exposed to media free of Ca^{2+} and Mg^{2+} for a shorter time. The cell suspensions from each species were diluted extensively with artificial seawater. The particle (cell) concentration in these nearly monodisperse suspensions was measured by haemocytometry. The collision efficiencies of both the two pure cell types alone and the mixtures of various proportions were then measured using a Couette viscometer to obtain a known shear rate.

The results are shown in Fig. 1. The points are fitted by the linear regression $y = 0{\cdot}137x + 14{\cdot}1$; $s_b = 0{\cdot}0196$, where y is the collision efficiency and x is the proportion of the more adhesive cell type. The relationship which would be obtained for 100 per cent specific adhesion is shown by the dashed line. The greatest difference between these plots is at $x = 50$ per cent. Applying tests given by Snedecor and Cochran[12] for the confidence limits of a

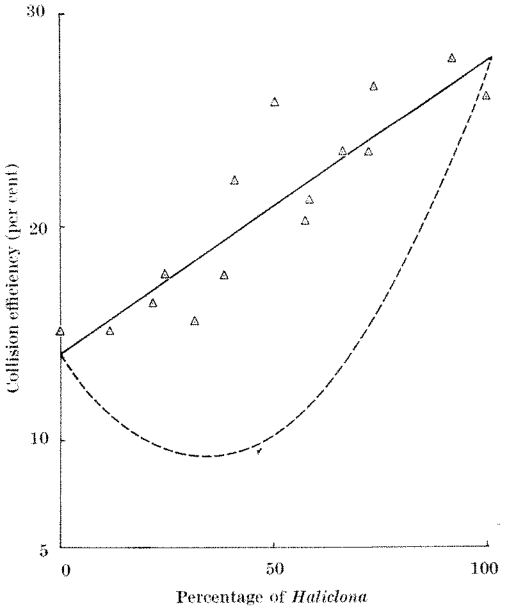

Fig. 1. Relationship between collision efficiencies (adhesiveness) and the proportion of *Haliclona occulata* cells in mixed suspensions of this species and *Halichondria panicea*. The full line shows the linear regression fitted to the plotted experimental points; the dashed line, that expected if a specific adhesion occurs.

regression, the 95 per cent and 99 per cent confidence limits are $\pm 1{\cdot}10$ and $\pm 1{\cdot}53$ for $x = 50$. The probability of 11 per cent of the adhesions being specific is $P < 0{\cdot}05$; for 15 per cent it is $P < 0{\cdot}01$. I therefore conclude that there is evidence against a general specificity of cell adhesion for these two species of sponge, though it cannot be excluded that a small proportion of cells might show specific adhesion. This, however, applies only to the behaviour of the cells during the first 40 min of re-aggregation and although Humphreys claimed that the specificity is manifest in this pair of species from the start of aggregation it is possible that the specificity only develops at a later time. Roth[13], for example, has suggested that specificity of adhesion only develops in mixtures of chick neural retina and liver cells after some hours of incubation.

Inhibition of Cell Aggregation by Antibodies directed against Actomyosin

IT has been proposed that cell adhesion involves the participation of actomyosin-like protein located in the surface[1]. The theory was based mainly on the similarity between actomyosin proteins in muscle[2-5] and non-muscle cells[6-8], a comparison of the properties of actomyosin protein with the effects of calcium and of nucleoside phosphates[9-11] on cell aggregation, and evidence indicating the presence of actomyosin-like protein at the surface of liver cells[12-15]. Hypothetical models have been suggested for the involvement of contractile actomyosin in intermolecular bonding between adjacent cells[16-18].

According to the actomyosin theory of cell adhesion, the adsorption at the cell periphery of antibodies directed specifically against the myosin–ATPase portion of these proteins should hinder their activity and reduce cell adhesiveness.

There is good evidence using fluorescent antibody techniques that the antigenic character of striated muscle myosin is different from that of the surface myosin-like protein of liver cells[15,19] and of thrombosthenin. Antibodies against human uterus actomyosin (UAM) reacted with the smooth muscle actomyosin of vascular[20] and intestinal origin and, in addition, with fibroblasts of connective tissue and thrombocytes (platelets), but not with skeletal or cardiac muscle, nor with the $(\text{Na}^+,\text{K}^+,\text{Mg}^{2+})$ dependent ATPase from human erythrocyte ghosts[21]. Antibodies against actomyosin from human striated pectoral muscle (PAM) reacted exclusively with skeletal and cardiac actomyosins[20]. Preimmunization serum did not react in the muscle, cell and ATPase systems already mentioned. Antibodies against actomyosin from the smooth muscle of human uterus (anti-UAM) and those against the actomyosin of human pectoral muscle (anti-PAM) blocked the activity of the Ca^{2+}-dependent myosin ATPase[22]. They also reacted—as demonstrated by immunofluorescent staining—with smooth and striated muscle fibres of bovine, rabbit, rat and chicken origin. Thus although type specific, the anti-UAM and anti-PAM were not species specific.

The fact that the anti-UAM antibodies specifically blocked the activity of the Ca^{2+}-dependent actomyosin ATPase and reacted with fibroblasts of connective tissue and thrombocytes, irrespective of species origin, suggested that the effect of anti-UAM could yield information on the aggregation of liver and muscle cells from chick embryos. We now report qualitatively reproducible results from aggregation experiments with anti-UAM and anti-PAM and discuss their bearing on the actomyosin theory of cell adhesion.

Highly purified actomyosins were prepared from fresh human surgical specimens of uterine[23] and pectoral[24] muscle. Antisera against UAM and PAM were obtained in rabbits by repeated intravenous injections of these preparations[25], and tested for specificity[20]. The skeletal muscle and liver tissue of 9 day old chick embryos were dissociated into separate cells by treatment with 0·25 per cent trypsin (Difco, 1 : 250) in Hanks's balanced salt solution for 10 min at 37° C (ref. 26).

Cell reaggregation was quantitatively estimated utilizing the gyratory shaker[27] and turbidimetric[28] methods; the cells were suspended and rotated in Eagle's minimal essential medium containing 10 per cent of the test serum. The muscle and liver cells were rotated in the gyratory shaker for 24 h, progress in aggregation being estimated by single cell counts and by an examination of samples taken from the test preparations. Changes in the absorbance of cell suspensions, which can be correlated with progress in aggregation, were assessed by the turbidimetric method[11,26,28].

In the presence of calf serum, pre-immunization serum (control preparations), or anti-PAM, both the liver and muscle cells after 24 h in the gyratory shaker had formed large compact aggregates. Those in the anti-UAM preparations were conspicuously smaller and less compact, and, in addition, about 20 per cent of the total number of cells (compared with about 5 per cent in the anti-PAM and control preparations) remained free. Cell viability tests using lissamine green stain[25] showed that the number of non-viable cells in the anti-UAM preparations was the same as in the anti-PAM and control preparations at the end of the test period, so that anti-UAM was not producing its inhibitory effect by impairing cell viability.

When preparations of muscle cells were rotated in the presence of anti-UAM, the decrease in absorbance was markedly less than for preparations of the same cells containing anti-PAM or control sera (Fig. 1). This is consistent with the aggregates formed in the anti-UAM preparations being considerably smaller than those in the anti-PAM and control preparations.

The specific reactive properties of the anti-UAM strongly point to the aggregation-inhibitory effect of the anti-UAM being an expression of its reaction with actomyosin-like protein located at the surfaces of the embryonic chick muscle and liver cells. Thus the antigenic property of the surface localized actomyosin-like protein of these cells must be similar, and, as indicated by the failure of the anti-PAM to produce the inhibitory effect, different from that of the myofibrillar actomyosin of the muscle cells. This is understandable, in terms of the difference between the antigenic property of striated muscle actomyosin and the surface localized actomyosin-like protein of liver cells[15]. The marked cell aggregation–inhibitory effect of the anti-UAM may therefore be interpreted as directly supporting the theory that cell adhesion involves the participation of surface localized actomyosin-like protein[1].

We thank Mrs Barbara Jones, Miss Barbara Morris and Mrs Alise Howes for technical assistance, and acknowledge

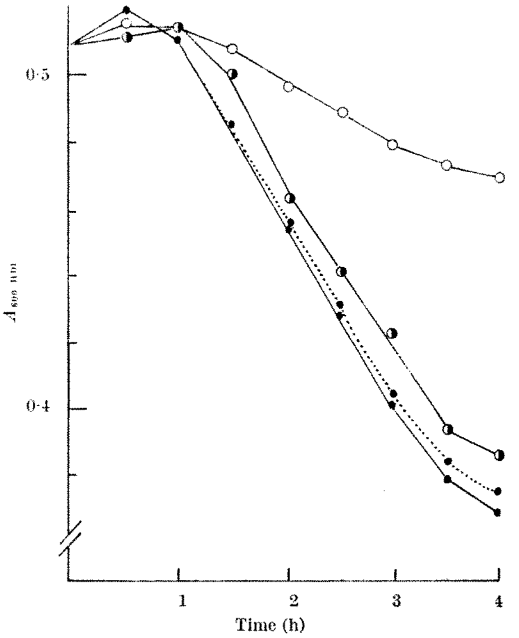

Fig. 1. The effects of anti-UAM, reactive with fibroblasts of connective tissue and thrombocytes, and of anti-PAM, on the absorbance of a rotated suspension of crude trypsin-dissociated cells from the muscle tissue of 9 day old chick embryos. Pre-immunization serum and calf serum were used as controls. ○—○, Anti-UAM (coincided with the production of small loosely formed aggregates with 20 per cent of the cells remaining free); ◑—◑, anti-PAM (well-formed aggregates comparable with those in control preparations); ●- - -●, pre-immunization serum and ●—●, calf serum (in each, production of large compact aggregates with only 5 per cent of the cells remaining free).

Homing of Lymph-borne Immunoblasts to the Gut

Between 3 and 6 days after antigenic stimulation, lymph nodes discharge large numbers of basophilic blast cells (immunoblasts) into the efferent lymph which carries them to the blood[1-3]. These cells contain many polyribosomes but little endoplasmic reticulum; nevertheless, they produce specific antibody[1,4,5] and are specifically cytotoxic *in vitro*[6]. Unlike small lymphocytes they incorporate DNA precursors with avidity and some of them transform into true plasma cells *in vivo*[7]. Immunoblasts produced by the caudal lymph nodes of rats can be obtained by collecting the thoracic duct lymph 3–6 days after antigenic stimulation of the hindquarter regions[8,9].

Because immunoblasts are released in large numbers before antibodies appear in the blood serum, it has been suggested that their most important function is to extravasate into the tissues and so provide, by local synthesis, the antibody that the blood is unable to supply[10]. This proposition was tested by collecting immunoblasts from rat thoracic duct lymph, labelling them *in vitro* with either ^{3}H-thymidine or ^{125}iodo-2-deoxyuridine and then injecting them intravenously into syngeneic recipients. The distribution of the labelled cells was then determined by autoradiography and scintillation counting.

Pure-line, SPF, male hooded rats, weighing about 220 g, were used. Donor rats were immunized by subcutaneous injections of an antigen given into the hind foot-pads, the glutei, the inner surface of the thighs and the flanks. The antigens used were *Brucella abortus* (Wellcome), BCG (Glaxo), sheep red cells or irradiated syngeneic sarcomata[8]. Three days later the thoracic ducts of four to six donor animals were cannulated and the lymph was collected in the usual manner[8]. Lymph collected over 8–12 h periods was pooled and the number of lymphocytes and the percentage of immunoblasts were determined[8]. Each pooled collection was incubated for 1 h at 38° C with 1 μCi/ml. of either ^{3}H-thymidine or ^{125}I-iododeoxyuridine (Radiochemical Centre, Amersham). The labelled cells were washed and finally resuspended in 2 ml. of medium 'TC199' and injected immediately into the tail vein of a recipient rat; a measured portion of the injection was retained for autoradiography and/or radio assay. Usually about 5×10^{8} total lymphoid cells were injected of which 10–20 per cent were labelled immunoblasts. At various times after the injection the rats were exsanguinated and killed and their viscera placed in 10 per cent formol saline. When immunoblasts labelled with ^{3}H-thymidine had been injected, sections were cut from various tissues and autoradiographs were prepared by standard techniques[8]. In this way, it was possible to see the exact microanatomical localization of the injected cells. The quantitative distribution of the injected cells was determined by counting the radioactivity in the organs of rats which had received immunoblasts labelled with ^{125}I-iododeoxyuridine. This thymidine analogue cannot be "re-utilized"[11-13] and has the further advantage that the γ-emission can be counted easily and accurately in a scintillation spectrometer (Packard, model 3002, 'Autogamma'). The results were expressed as a percentage of the total radioactivity injected and also as a specific activity in terms of counts per minute per unit wet weight. Biochemical analyses confirmed that all the activity was associated with macromolecular nucleic acids.

In these experiments twenty recipient rats and one hundred donor rats were used. The distribution of the injected cells was the same whatever the nature of the antigen that had been used to stimulate the donor animals. Immediately after injection many of the injected cells were retained temporarily in the lungs, liver and spleen, but thereafter the number of cells in these organs declined and labelled cells began to appear in the walls of the gut.

Table 1. THE DISTRIBUTION OF RADIOACTIVITY IN VARIOUS ORGANS 24 H AFTER THE INTRAVENOUS INJECTION OF 4×10^7 SYNGENEIC IMMUNOBLASTS LABELLED WITH ^{125}I-IODODEOXYURIDINE

Tissue	Percentage of total activity injected	Specific radio-activity (c.p.m./g)
Lung	0·5	1,500
Liver	2·0	800
Spleen	2·8	16,000
Small gut	21·0	19,500
Large gut	2·7	6,400
Mesenteric lymph nodes	0·5	10,000
Peripheral lymph nodes	0·1	1,000

This process was well established by 1 h and complete at 5 h. After this time the distribution of cells remained relatively constant until 24 h which was the longest time studied (Table 1).

In all rats killed 5 h or more after injection the small gut always contained most of the radioactivity that could be recovered from the viscera, sometimes as much as 40 per cent of the injected dose. This was confirmed by autoradiographic studies which showed a massive infiltration of the lamina propria by labelled cells which were present both at the bottom of the crypts and well up into the villi (Fig. 1). Very few labelled cells gained entry into the Peyer's patches, however, and it was clear that the immunoblasts play no immediate part in populating these tissues. Similarly, the total number of labelled cells in all the other macroscopic lymphoid organs—spleen, lymph nodes and thymus—never exceeded 20 per cent of that in the small gut. In other words, for every immunoblast that reached an actual lymphoid organ four or five went to the small gut. Every organ examined contained some activity and labelled cells were seen in the mucosa of the trachea, the parenchyma of the lung, in the kidney and in the salivary glands.

It was shown originally by Gowans *et al.*[14,15] that when small lymphocytes were injected intravenously most of them entered the spleen, lymph nodes and the Peyer's patches and many of them regained the lymph and continued to recirculate. But the few large lymphoid cells that were injected became localized in the lamina propria of the small gut[16] and this observation has been confirmed[17]. Our results are in accord with these findings and further indicate that most immunoblasts that are generated in lymphoid tissue remote from the gut, in response to varied antigenic stimuli, are destined for the lamina propria of the small gut. Because many of these cells are probably plasmablasts[7] it seems likely that they may be particularly concerned with furnishing the IgA antibodies that protect mucous surfaces in general and the gut in particular[18-22]. In any case the cellular economy of any immune response must involve a substantial investment in the lamina propria of the gut and any assessment of the antibody response will be incomplete unless the antibody content of the mucosa and external secretions is taken into account.

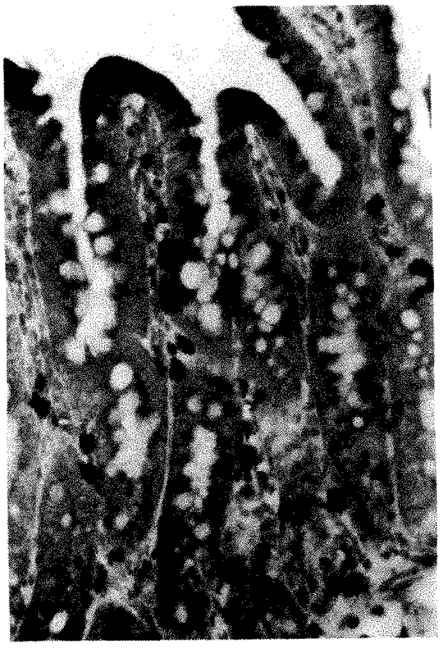

Fig. 1. Photomicrograph of an autoradiograph of a 4 μm section cut from the small gut of a rat 20 h after the intravenous injection of syngeneic immunoblasts that have been labelled *in vitro* with ^{3}H-thymidine. Note the large number of labelled cells in the lamina propria.

We thank Drs E. J. Delorme and K. M. Rudenstam for preparing some of the thoracic duct cannulations and Dr T. Gillman (ARC, Babraham, Cambridge), who confirmed some of our autoradiographic results. The investigation was supported by a grant to the Institute of Cancer Research from the British Empire Cancer Campaign for Research.

Association of ^{3}H Corticosterone-1,2 with Macromolecules extracted from Brain Cell Nuclei

CORTICOSTERONE, the principal adrenal steroid in the rat, is retained by cell nuclei in the brain of adrenalectomized rats by a process specific to the corticosterone structure[1]. Nuclear binding of hormone is greatest in the hippocampus, where we have previously found the highest tissue concentration of radioactive hormone, but is also significant throughout the rest of the brain[1,2]. The binding of steroid hormone to cell nuclei in other target tissues indicates that the hormone receptor is protein which can be extracted from the nuclei by moderate salt concentrations[3-6]. We now present evidence that hormone within brain cell nuclei is bound to a macromolecular component, probably protein, which can be extracted from isolated nuclei by 0·4 M NaCl.

Male albino rats, adrenalectomized 4–7 days previously[1,2], were injected with 100 μCi of corticosterone (specific activity 40 Ci/mmole, New England Corp., Boston,

The brain regions from which nuclei were isolated are as follows: hippocampus, cerebral cortex, and HTM, a pooled sample consisting of hypothalamus, thalamus, and midbrain. For dissection procedure, see ref. 1. Nuclei from each region were extracted successively with solutions of the salt concentration indicated. s.a.: specific activity, counts per min per microgram of protein.

Mass.) intraperitoneally, or via the carotid artery after acute partial hepatectomy, and were killed by decapitation 1 h later. Nuclei were isolated from whole rat brains and from selected brain regions as described elsewhere[1]. The highly purified nuclei were treated with a standard buffer (0·1 M Tris-HCl, *p*H 7·4; 0·5 mM EDTA, 50 mM $MgCl_2$, 5 mM β-mercaptoethanol) containing various concentrations of sodium chloride solution and centrifuged at 16,000 r.p.m. for 10 min to sediment nuclei and chromatin fragments.

In the first experiments we determined the ionic strength necessary to release the steroid radioactivity from nuclei. Nuclei isolated from brains of adrenalectomized rats injected intraperitoneally with 100 μCi ^{3}H corticosterone were extracted successively with buffer containing 0·4, 0·6, 1·0 or 2·0 M NaCl. Radioactivity was extracted with toluene scintillation fluid and counted in a liquid scintillation counter, and the macromolecular components were precipitated with 10 per cent TCA in 50 per cent ethanol and dissolved in KOH for protein analysis by the method of Lowry *et al.*[7]. Table 1 shows the results of these experiments and it can be seen that the largest amount of radioactivity was extracted by 0·4 M salt. This fraction also had the highest concentration of radioactivity per microgram of protein. As we have reported elsewhere[2], the largest concentration of radioactivity occurred in nuclei from the hippocampus. Lesser but still significant amounts of radioactivity were found in cortex and HTM nuclei, and this showed the same extractability with increasing salt concentration as did the radioactive steroid in hippocampal cell nuclei.

We also used gel filtration on 'Sephadex' to determine the percentage of radioactive hormone, extracted by 0·4 M salt at *p*H 7·4, which is bound to macromolecules. For these experiments, rats were administered 100 μCi corticosterone in saline via the carotid artery after acute removal of the two largest lobes of the liver. These two procedures increased by eight to ten-fold over intraperitoneal injection the amount of ^{3}H-corticosterone which enters the brain. Approximately 1 ml. of extract was placed on a 1·0 × 23 cm column of 'Sephadex *G*-200' suspended in 0·4 M salt in the standard buffer. Thirty ml. of the medium was used to elute the column and sixty fractions were collected with an automatic fraction collector. A typical run is presented in Fig. 1, and shows that nearly 40 per cent of the radioactive hormone is eluted with a protein peak consisting of macromolecules of greater than 800,000 molecular weight[8] which are completely excluded from the 'Sephadex' beads. The remainder of the radioactivity is eluted at the end as free steroid after the rest of the protein has been eluted. In five experiments, an average of 41·6 ± 1·4 per cent of the radioactive hormone was eluted with the macromolecular peak. The presence of free steroid in the extract is not surprising for we have found that, on storage overnight at 4° C, the complex is quite unstable and most of the bound steroid is released from the macromolecular fraction.

It is likely that the peak of macromolecular material in which the bound hormone is eluted (Fig. 1) is an aggregate, possibly artificial, of protein and nucleic acid molecules. Overnight storage of the extract at 4° C has been found to result in a decrease in the highest molecular weight peak and the appearance of lower molecular weight species. Such a dissociation of salt extracts of nuclei into smaller sized fractions by treatment with deoxyribonuclease and ribonuclease has been reported for the oestradiol-binding proteins from the uterus[3]. There is very little DNA in the 0·4 M salt extract of rat brain nuclei, less than 4 μg/mg of protein, and approximately 35 μg of RNA per mg of protein in the extract. Concentrations of DNA and RNA per mg of protein in intact rat brain nuclei are 147 and 53 μg, respectively. Pretreatment of the 0·4 M extracts of rat brain nuclei containing ^{3}H-corticosterone with deoxyribonuclease and ribonuclease has no effect on the binding of hormone, while pretreatment with trypsin for 1 h at 4° C reduces the amount of bound hormone by 40 per cent.

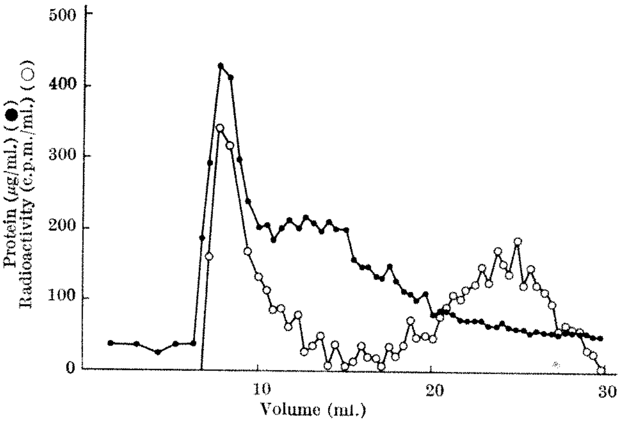

Fig. 1. Elution pattern of protein (●—●) and c.p.m. (○—○) in a 0·4 M NaCl extract of rat brain nuclei labelled with ^{3}H corticosterone-1,2 from a 'Sephadex *G*-200' column. Protein was determined directly on 0·1 ml. of eluate by the method of Lowry *et al.*[7], and radioactivity was extracted directly from 0·1 ml. of eluate with toluene scintillation fluid. The high baseline of protein is due to the colour produced by the standard buffer.

From these results and those from other laboratories on nuclear hormone binding factors, it seems highly probable that the binding substance is a protein of a type which is believed to have a regulatory function in the cell nucleus over RNA and subsequent protein synthesis[9,10]. We are at present attempting to purify the corticosterone-binding macromolecules from brain cell nuclei and to determine a regulatory role for this substance.

Shared Viral Antigen of Mammalian Leukaemia Viruses

IN 1966, Geering, Old and Boyse[1] identified group-specific (gs) antigens of murine leukaemia viruses (MuLV) in immunoprecipitation tests with antigen in the form of disrupted virions or extracts of infected tissue. Antisera containing a wide range of precipitating MuLV antibodies are obtained from inbred rats bearing large subcutaneous transplants of syngeneic leukaemias induced by wild-type Gross virus[1]. Usually a large number of rats have to be screened in order to find one with antibody to the complete set of MuLV antigens known to be demonstrable by immunoprecipitation. Rats which have both a massive local tumour and metastasis to local lymph nodes, and which have survived for a comparatively long time after they received the leukaemic transplants, are most likely to yield such antisera.

Gregoriades and Old isolated and partially characterized one of the soluble gs antigens, MuLV-gs1 (ref. 2); a gs antigen with similar properties has been studied by Schäfer *et al.*[3]. Another of the MuLV gs antigens, MuLV-gs3, is now known to be shared by the feline leukaemia virus (FeLV)[4]. Leukaemia viruses of C or enveloped A type[5] have been found in primary and transplanted tumours of the rat and hamster (refs. 6–12 and personal communications from P. Sarma and H. Chopra) as well as in cats and mice; Fig. 1 illustrates their morphological similarity to MuLV and FeLV. We now report that antigen gs3 is present in these viruses also.

The rat virus was obtained from the peritoneal fluid of rats bearing the Novikoff ascites hepatoma, and the hamster virus from washings of minced D–9 lymphosarcoma[11,12]. In each case the virus was isolated by density gradient centrifugation in potassium tartrate as previously described for MuLV and FeLV[2,4,13]. (The band is at 1·3 g/cm^3 for D–9 virus[14] and about 1·15 g/cm^3 for Novikoff virus.) Soluble components were released by treatment with ether[1]. Ouchterlony tests were performed in 2 per cent agar ('Immunoplate' pattern C, Hyland, Los Angeles).

Fig. 2 illustrates the presence of gs3 in the mouse, cat, hamster and rat leukaemia viruses. The major antigens of MuLV, gs1 and gs2 (fused heavy band in Fig. 2), are absent from the cat, hamster and rat viruses; gs3 antigen in the MuLV preparation is obscured in this illustration by the intense reaction of the other gs components. No serological cross-reaction between the mammalian and avian leukaemia viruses has been observed (Fig. 2 and refs. 4 and 14).

When this shared antigen was first identified in MuLV it was designated MuLV-gs3. Because the same antigen has now been found in two other species of Rodentia as well as in one species of Carnivore, the notation is no longer appropriate, for the group of viruses which it characterizes is not confined to the mouse. But perhaps the problem of re-naming it should be dealt with later when more is known about the comparative immunology of mammalian leukaemia viruses.

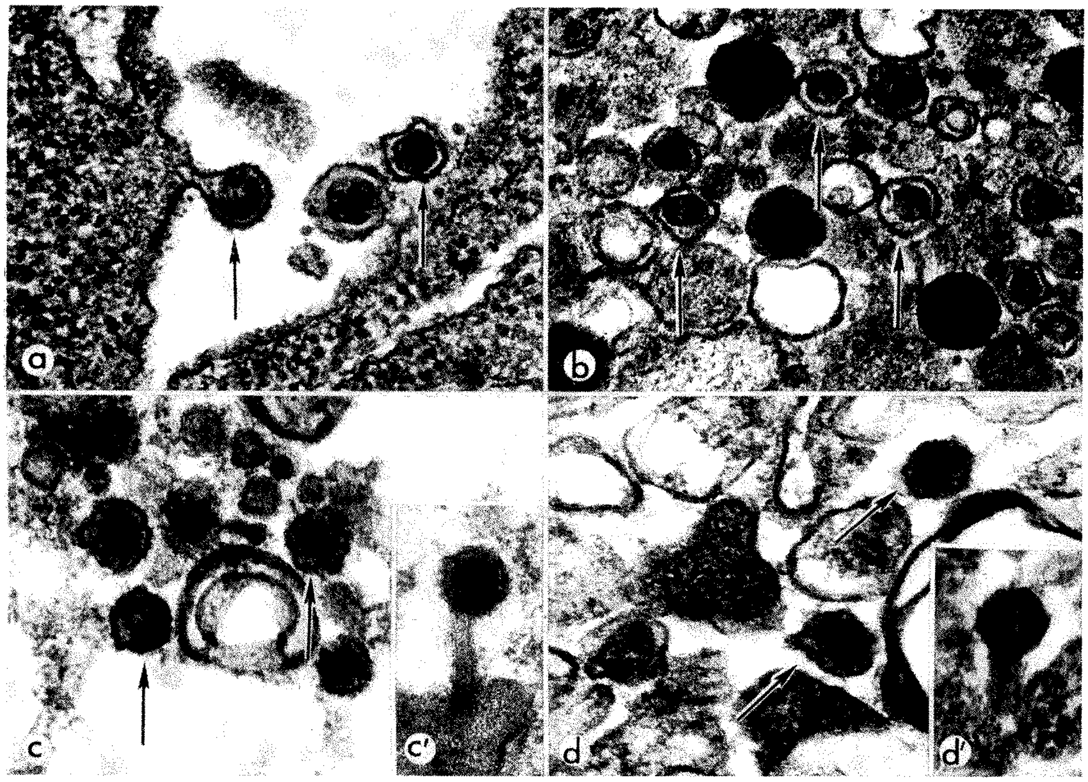

Fig. 1. Virus of type C or type A morphology occurring in different mammalian species (× 69,600). (*a*) C57Bl/6 mouse leukaemia induced by passage A Gross virus; C-type particles and an enveloped A-type particle budding from the cell surface. (*b*) Novikoff rat hepatoma, ascitic form; many C-type particles in a pellet prepared from ascitic fluid. (*c*) Cat lymphosarcoma; C-type and enveloped A-type particles in the intercellular space; insert (*c'*) shows budding figure of an enveloped A-type particle. (*d*) Hamster D–9 lymphosarcoma; enveloped A-type particles; insert (*d'*) shows budding figure of an enveloped A-type particle. Samples were fixed in 1 per cent glutaraldehyde and then in 1 per cent OsO_4, and embedded in 'Epon'. Thin sections were stained with uranyl acetate and lead citrate, and examined with a Siemens 'Elmiskop 1A' electron microscope.

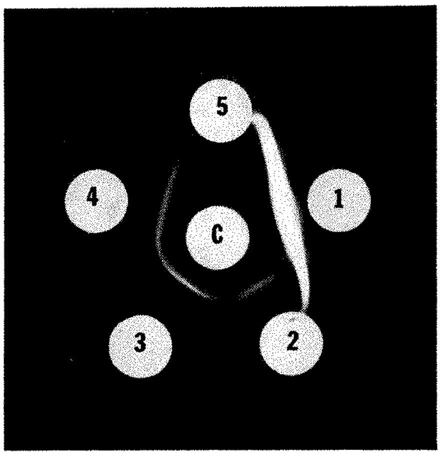

Fig. 2. Centre: MuLV antiserum. Peripheral wells: ether-disrupted virus from (1) mouse (MuLV); (2) cat (FeLV); (3) hamster (D-9 lymphosarcoma); (4) rat (Novikoff hepatoma); and (5) chicken (BAI strain A of avian myeloblastosis virus). The antigen shared by the mammalian leukaemia viruses is gs3.

We thank Drs J. J. Trentin and W. A. Stenback (Baylor University College of Medicine, Houston, Texas) for the hamster D-9 lymphosarcoma and Dr J. W. Beard (Duke University School of Medicine, Durham, North Carolina) for the avian myeloblastosis virus. The work is supported in part by an NCI grant and a grant from the John A. Hartford Foundation, Inc.

Suppression of Autoimmune Disease in NZB and $(NZB\times NZW)F_1$ Hybrid Mice by Infection with Malaria

VARIOUS immunological changes have been observed in many apparently healthy subjects living in tropical regions that are probably related to multiple parasitic infections from childhood[1]. Consideration of this in conjunction with the rarity of autoimmune disease in tropical Africa, for example Western Nigeria[2], led to the suggestion that the immunological effects of repeated parasitic infection might have some protective action against the development of autoimmune disease[2]. To investigate this hypothesis we have studied the effects of infection with malaria on the spontaneous autoimmune disease of NZB mice and the $(NZB\times NZW)F_1$ hybrid mice (B/W mice). Twenty-one NZB mice and thirteen female B/W mice from the Taplow colony were infected, when one month old, with the rodent malaria parasite *Plasmodium berghei yoelii*[3] by the intraperitoneal injection of 1×10^6 parasites derived from a heavily infected mouse of the same strain. The malaria strain was not contaminated with *Eperythrozoon coccoides*. Parasitaemia was monitored by the examination of Giemsa stained blood films made from the tails of the mice every second day during the acute phase of the infection and at longer intervals thereafter. To determine whether low parasitaemia was persisting, heparinized blood samples were collected from each mouse 4 months after infection and pooled samples injected into young BALB/c mice.

Blood and 24 h urine samples were collected from all infected mice at monthly intervals. Direct Coombs tests were performed using a rabbit anti-mouse globulin antiserum which gave strong lines with mouse IgG and IgM on immunoelectrophoresis. Sera were tested for antinuclear factor at a dilution of 1 : 10 using rat liver as substrate. A quantitative protein estimation was carried out on an aliquot of each 24 h urine sample using sulphosalicylic acid. Cryostat sections from snap-frozen kidneys removed from some of the mice were examined for the presence of immunoglobulin deposits by direct immunofluorescence.

Table 1. FEATURES OF THE PARASITAEMIA OF NZB AND B/W MICE INFECTED WITH *Plasmodium berghei yoelii*

Mouse strain	Peak parasitaemia (Parasites/10^4 erythrocytes) Mean	Range	Duration of parasitaemia (days) Mean	Range
NZB	$1,570\pm 273$	600–2,920	$19·2\pm 0·44$	18–22
B/W	$1,920\pm 418$	718–5,350	$12·6\pm 0·22$	12–14

The pattern of disease occurring in the infected mice was compared with that previously observed in control animals from the Taplow colony. Four control mice from each strain were studied in parallel with the mice infected with malaria. The pattern of disease in these animals closely followed that previously observed in the larger control groups studied at Taplow. Five malaria-infected NZB mice and two infected B/W mice were killed within the first three months of life in order that their kidneys could be examined for features of complex nephritis.

The parasitological features of the malaria infection in the two strains of mice are shown in Table 1. All the mice of both strains inoculated with *P. berghei yoelii* became infected. The NZB mice had a longer period of parasitaemia than the B/W mice but the latter strain had a higher peak parasitaemia. No parasitaemia resulted from the sub-inoculation of pooled blood obtained from any of the infected mice 4 months after infection, indicating that persisting infection was not present.

Control female B/W mice developed severe proteinuria when 6–8 months old and 97 per cent had died by the age of 11 months (Fig. 1). At the age of 9 months 58 per cent of the control mice gave a positive test for antinuclear factor. By contrast the eleven B/W mice infected with malaria were all alive at 11 months and none had developed proteinuria or a positive test for homogeneous antinuclear factor. The differences between control and infected mice with regard to mortality at 11 months, proteinuria at 11 months and incidence of positive antinuclear factor at 9 months are all statistically significant ($P<0·01$).

Three of the malaria infected B/W mice were killed at 12 months. The kidneys of these mice contained only small deposists of immunoglobulin by contrast with the heavy deposits seen in the kidneys of control animals examined at 7 or 8 months.

The onset of a positive Coombs test in the NZB mice infected with malaria was delayed in comparison with the controls (Fig. 2). The number of malaria infected mice with a positive Coombs test at 9 months (four of the sixteen) is significantly lower than the number of control animals with a positive test at the same age (sixteen out of seventeen) ($P < 0.01$). By 12 months, however, no significant difference was evident in the proportion of mice with a positive Coombs test between the malaria infected mice and the controls. At 12 months the mean packed cell volume was similar in both groups.

These experiments indicate that the early infection with the rodent malaria parasite *P. berghei yoelii* is associated with a delay in the onset of haemolytic anaemia in NZB mice and is associated with protection against the development of renal disease in B/W mice. The mechanism by which the malaria infection modifies the course of these autoimmune diseases remains a matter for speculation. Although the malaria strain used in the present study had been passaged in blood only twice since mosquito passage, it may have been contaminated by passenger viruses. It is therefore possible that the protective effect of the malaria infection was a result of these viral contaminants rather than of the malaria parasite itself. There is evidence that viral infection is important in the induction of autoimmune disease in NZB mice[4], and interferon production by the malaria parasite or its contaminants may have had a deleterious effect on the causative virus. On the other hand, the failure of the interferon inducer 'Statolon' to influence the onset of Coombs positivity in NZB mice is evidence against this hypothesis[5].

At the height of malaria parasitaemia the immune response of infected mice to sheep cells is reduced[6], but it seems unlikely that suppression of the effector immune response would persist for a prolonged period after recovery from the parasitaemia. It seems more likely that infection with malaria enables NZB and B/W mice to maintain tolerance to an antigen, possibly of viral origin, which usually induces a harmful immune response.

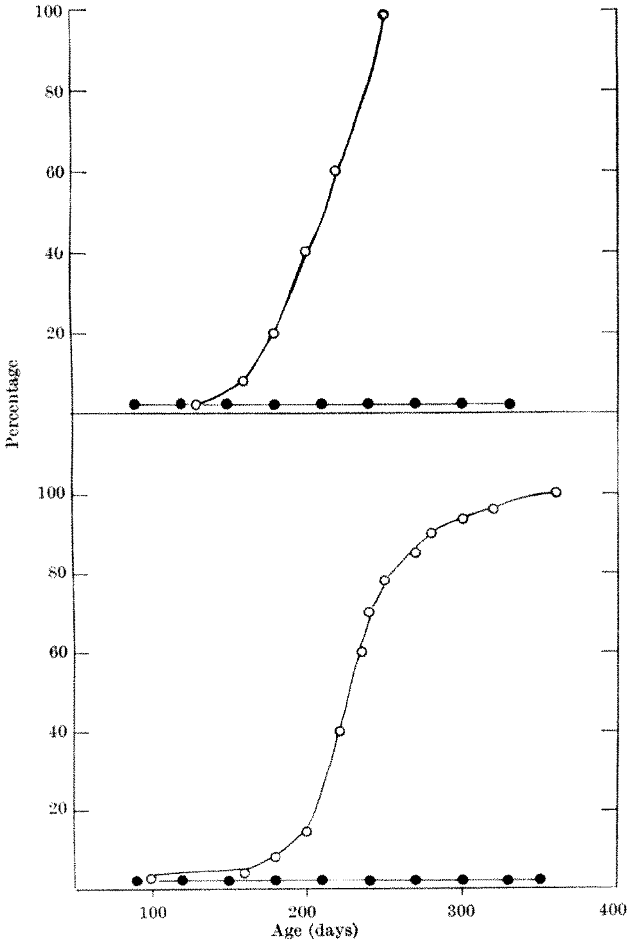

Fig. 1. Top, incidence of proteinuria greater than 10 mg/24 h in eleven malaria infected female B/W mice and in forty female controls. Bottom, cumulative mortality curve for eleven malaria infected female B/W mice and 101 female controls. ●—●, Mice infected with *P. berghei yoelii*; ○—○, controls.

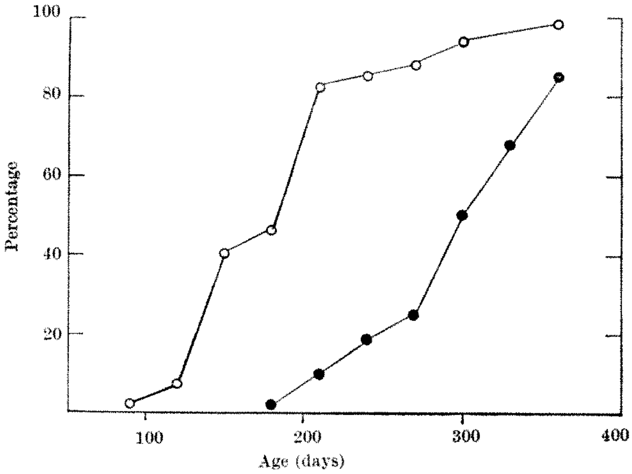

Fig. 2. Incidence of a positive Coombs test in sixteen malaria infected NZB mice and in seventeen controls. ●—●, Mice infected with *P. berghei yoelii*; ○—○, controls.

Considerable caution is needed in extrapolating the results of these animal experiments to a consideration of human disease. They do, however, support the idea that repeated parasitic infections may have some protective action against the development of autoimmune disease in man. Elucidation of the mechanism by which infection with *P. berghei yoelii* suppresses autoimmune disease in mice might indicate a new approach to the treatment of human autoimmune disease.

We thank Dr A. M. Denman for providing us with data from control NZB and B/W mice and for encouragement during this study, and Mrs D. Green for technical assistance.

Changes in Leptomonads of *Leishmania tropica* grown in Media containing Immune Serum

THE method for differentiating strains of *Leishmania*, introduced by Adler[1,2], is to grow them on Locke–serum–agar (semi-solid medium) or on Rugai's medium to which homologous or heterologous immune serum is added. After 3 or 4 days of cultivation, the formation of large

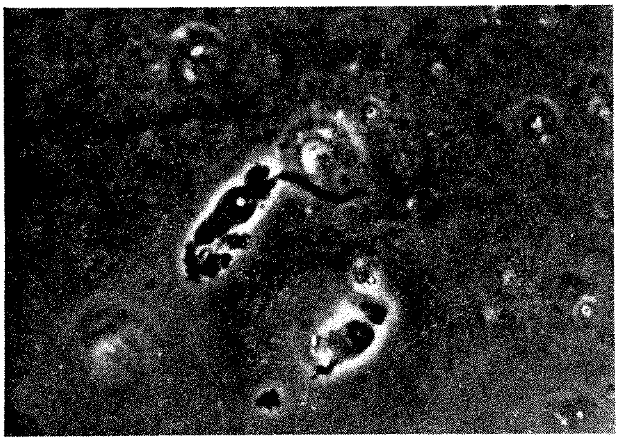

Fig. 1. *Leishmania tropica* on homologous immune serum 1 : 20. Fresh preparation; 6 h culture; ×1,000, phase-contrast. Note pyriform cell, enlarged flagellar vacuole, vesicle at base of flagellum.

irregular, aflagellar cell masses, containing an accumulation of various granules, can be observed. These cell masses were initially considered to be syncytia from which flagellar forms were assumed to re-differentiate at a later stage. Observations made on younger cultures aroused some doubts, however, regarding the nature of these syncytia (personal communication of S. Adler) and we therefore decided to follow up changes produced in the leptomonads by examination of cultures at short intervals, especially during earlier stages of cultivation.

For experimental purposes, flagellates form 4 to 5 day old cultures of the Ein Gedi II strain, routinely maintained at 28° C on Locke–serum–agar with rabbit haemoglobin, were inoculated on Locke–serum–agar or on Rugai's medium to which immune rabbit serum was added in the ratio 1 : 20 (normal serum in control media). The immune serum was prepared in rabbits by six intravenous injections of flagellates at 6 day intervals. The rabbits were bled 10 days after the last injection. Observations were carried out by simple and phase microscopy directly on drop samples of fresh, untreated, or trypan-blue stained preparations, as well as on air-dried smears stained with May–Grünwald stain.

The observed changes involved extracellular and intracellular phenomena. In the medium, a precipitate consisting of flake-like aggregates formed immediately on addition of unwashed leptomonads. In some sera the precipitate persisted for several days, the aggregates enveloping the cells; in other sera the minute droplets which constituted the aggregates coalesced to form hyaline bodies, encompassing single cells or cell groups. The precipitate is a complex of exo-antigens[3] or metabolites accumulating in the maintenance medium, and the antibody in the experimental medium. This could be proved in the first 30 h of cultivation by staining the washed precipitate with a sheep anti-rabbit globulin, conjugated with fluorescein isothiocyanate. By the third day the complex apparently underwent some changes, for it no longer stained with the conjugated globulin. Fluorescence was also observed on the cell surface. No precipitate was formed when the inoculum was washed several times with phosphate-buffered saline before it was added to the experimental medium, whereby changes in the cells were delayed for several hours.

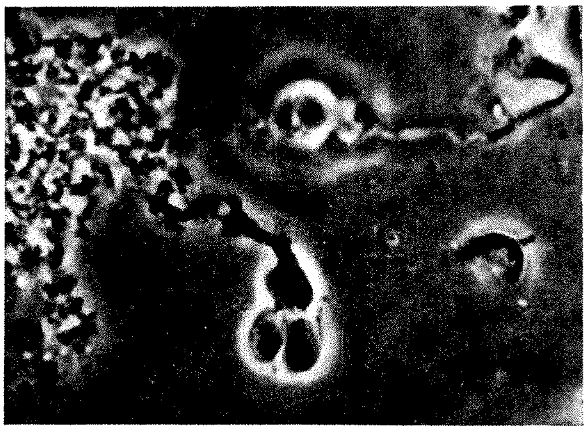

Fig. 2. *Leishmania tropica* on homologous immune serum 1 : 20. Fresh preparation; 16 h culture; ×4,200, phase-contrast, electronic flash. Cell after division. Note daughter cells held together by vesicle formed at base of flagellum and extending almost to tip; precipitate at left.

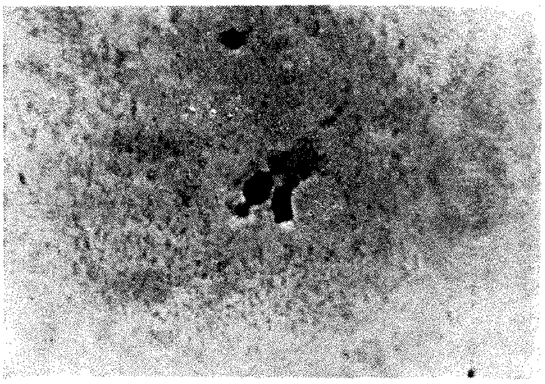

Fig. 3. *Leishmania tropica* on homologous immune serum 1 : 20. May–Grünwald phase-contrast; ×1,000. Same stage as Fig. 2. Note vesicle moulded around original flagellum; flagella of daughter cells embedded in vesicle.

Intracellular changes involved an almost immediate immobilization of the cell body and gradual slowing of flagellar movement until it ceased. The cells became pyriform, the flagellar vacuola enlarged and a small spherical vesicle was formed around the base of the flagellum (Fig. 1). The vesicle then spread and finally encircled the entire flagellum. After the first division, the daughter cells, observed by phase microscopy, appeared spherical and held together by the vesicle and the flagellum (Fig. 2). On staining with May–Grünwald stain, however, it became evident that each spherical daughter cell had a separate flagellum (Fig. 3). As cell division continued, groups of cells, the progeny of a single leptomonad, were formed, each with its own flagellum, all held together by the vesicle. Such groups of cells, embedded in the flake-like precipitate or united by hyaline material, formed the cell clumps, originally described as "syncytial" masses (Fig. 4). The granular centre of the clump consisted of precipitate, detached flagella and cell debris. On the surface of the clumped cell, division continued and after 3 to 4 days normal, elongated cells were seen. Adler considered the emergence of these cells as resulting from a decrease of antibody concentration in the medium[2].

The presence of immune serum in the medium does not interfere with normal mitosis. Descendants of a single cell are held together by the vesicle. The immune serum, however, presumably produces alterations in the cell membrane which cause leakage with vesicle formation and rounding of the cell body; it may, moreover, contribute to changes in the intracellular metabolic processes[4] which would lead to an accumulation of various granules as observed by Adler[2].

We thank Drs M. Giladi-Eyal, T. Dishon, Mr E. Kennedy and Mr A. Niv for their help. This work was supported in part by a US Public Health Service research

Changes in the Electrical Impedance of Blood during Coagulation

Reports on the impedance changes of blood during coagulation have been conflicting, and many have concluded that there is no significant impedance change which could be related to the coagulation process[1-5]. In 1948, however, Rosenthal and Tobias[6], using improved techniques, demonstrated a significant increase in impedance following coagulation, but the technique never came into practical use. Moreover, though some workers confirmed the observations[7], others claimed to obtain conflicting results[8].

Earlier difficulties in measuring blood impedance changes during coagulation were due not only to insensitive instruments[9] but also to the masking effects of cell sedimentation, particle disintegration, temperature changes, agitation, and so on[2,5,10-12]. Practical application was therefore abandoned[9], and the only device using electrical conductivity in any way is the "fibrin-switch" which is, essentially, a mechanical device[13,14].

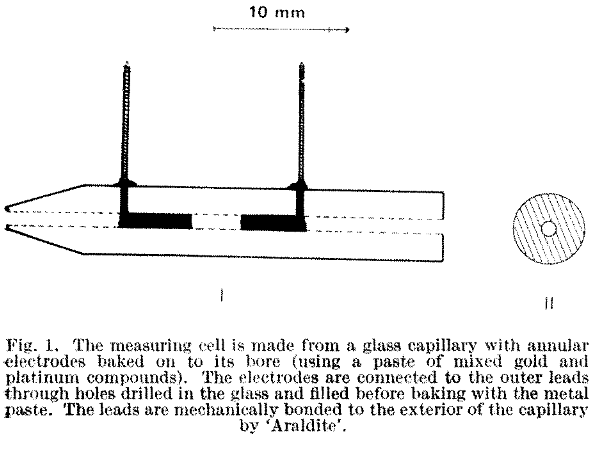

Fig. 1. The measuring cell is made from a glass capillary with annular electrodes baked on to its bore (using a paste of mixed gold and platinum compounds). The electrodes are connected to the outer leads through holes drilled in the glass and filled before baking with the metal paste. The leads are mechanically bonded to the exterior of the capillary by 'Araldite'.

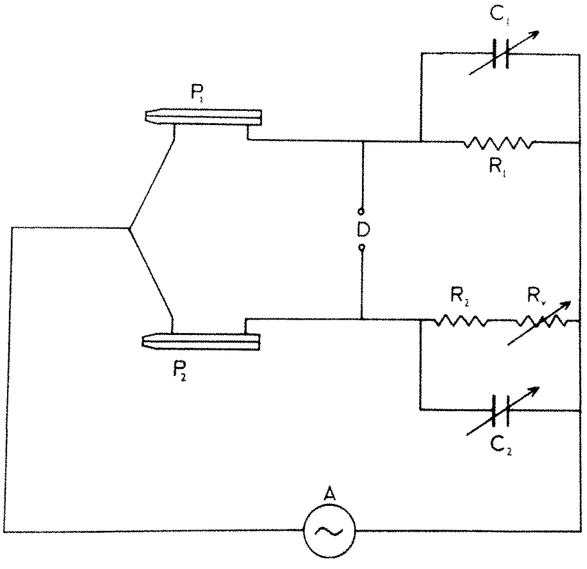

Fig. 2. The measuring bridge. P₁ Reference (heparinized) cell; P₂, measuring cell; R₁, fixed resistor of 15 kΩ; R₂, fixed resistor of 10 kΩ; Rv, 10 turn helipot of 10 kΩ; C₁ and C₂, variable capacitors of 250 pF; D, oscilloscope having sensitivity of 1 mV/cm; A, oscillator providing 1·2 V, 10 kHz sinusoidal tension.

A new principle is described here, which enables impedance changes caused by the clotting mechansim to be isolated from those caused by other processes in the blood. It allows continuous undisturbed impedance monitoring of the blood sample with a clear indication of the clotting time. The principle on which this work is based may, moreover, be useful in studies on cultures of microorganisms and the effect of antibiotics on such cultures; studies of antigen–antibody reactions; and other investigations of reactions in liquid systems.

The electrical impedance of a cell (Fig. 1) containing the clotting blood is measured in a bridge circuit (Fig. 2) in which the balancing resistance consists of a similar cell, containing blood from the same sample, but in which coagulation has been prevented by the addition of about 1 µl. of 5,000 U/ml. heparin. All impedance changes are therefore balanced but for those resulting from coagulation. The method also excludes impedance variations arising from individual differences in haematocrit, electrolyte concentration, urea concentration, and so on, all of which affect impedance of the blood[12].

The bridge was supplied with 1·2 V, 10 kHz sinusoidal tension. The blood, collected from finger puncture in a pipette, was divided between the measuring cells, the reference cell (containing the heparin) being filled last. In early experiments, the bridge was continually balanced by adjusting the helipot R_2 and the variable capacitors at predetermined time intervals (for example, 30 s) and the results were obtained from the helipot scale. Later, the output voltage from the bridge was recorded on a continuously running chart recorder with the bridge offset by reducing R_2 from the original balance point so that the balance point was avoided during recording.

The variation of electrical impedance of a blood sample during coagulation was highly reproducible in several hundred tests. Fig. 3 illustrates the typical decrease in the impedance during the first 12 min, followed by a less steep increase. Both the descending and ascending parts of the curve contained secondary steps of characteristic form.

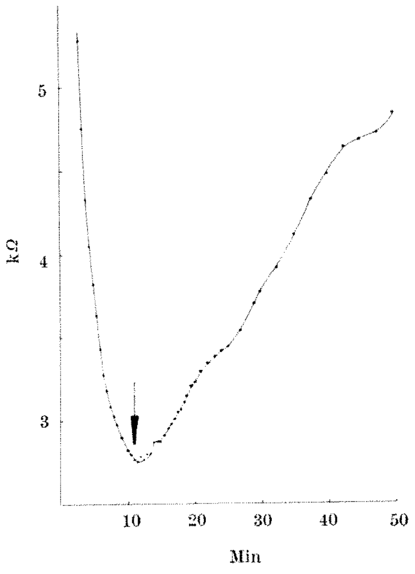

Fig. 3. The changes in blood impedance during coagulation. The ordinate represents the values of the helipot as the bridge was continually balanced. The arrow points to the coagulation time of the control samples.

The relationship of the curve to the coagulation process was examined as follows: A blood sample, collected in a pipette, was divided among five cells; first to be filled was the bridge cell in which the clotting was to occur, then three identical cells which served as controls and finally the reference bridge cell containing heparin. All cells were filled within 30 s. While the impedance changes were recorded, the control cells were checked for the appearance of clot, by probing the blood in the first cell with a wire hook at 30 s intervals. After clotting of the blood in the first control cell, the other two were successively examined. The time at which a solid clot was found in the third cell is represented in Fig. 3 (arrow). In a series of such experiments clotting was within 30 s of the minimum of the impedance curve. Improvement of the technique—by consistent techniques of blood collection and manipulation of the cells—reduced the scatter of the minima. Experiments on different days on blood of the same subject did, however, show variations, which are probably physiological.

Impedance measurements were performed also in experiments where: (*a*) both sample and reference cells were filled with clotting blood; (*b*) both cells were filled with heparinized blood; (*c*) the reference cell was replaced by a constant resistor while the sample cell was filled with clotting blood. The curves obtained in experiments (*a*) and (*b*) were relatively flat and the fluctuations recorded a higher amplification were not reproducible. The curves obtained in experiment (*c*) had various forms which were not reproducible and had no specific pattern which could be related to the coagulation process.

This method enables interpretation of some of the conflicting results obtained by previous workers. Rosenthal and Tobias were able to obtain curves which closely resemble the ascending branch of the curve displayed in the present work. It seems, moreover, that their data show the prominent step of the ascending branch, but in plotting the curves they preferred to ignore this step (Fig. 5 of ref. 6). Their readings also correspond to part of the descending branch, but they assumed these higher readings to be caused by temperature variations or by insufficient time for thorough wetting of the electrodes, and excluded them (Figs. 4 and 5, ref. 6). They concluded therefore that before clot formation there is no significant change in resistance. On the other hand, Mungall *et al.*[8] obtained initial decrease in impedance, and probably being unaware of the data ignored by Rosenthal and Tobias, interpreted their findings as conflicting with those of the latter. Errors in earlier studies can also be attributed to the neglect of factors such as agitation; the ratio of the volume of the sample to its area contacting the container; surface properties; and temperature. Unless these factors are taken into account[15-18], the value of any correlation is doubtful.

The causes for the typical impedance changes displayed in Fig. 3 are not certain. The curve might represent several processes which affect the impedance, some of them in opposing directions. Thus, the beginning of the clotting process might be dominated by disintegration of corpuscles (platelets) and degradation of certain proteins which would increase the number and the mobility of the charged particles. The increasing impedance following coagulation has been related to clot retraction and solidification[6,7,19]. The formation of a fibrin network, the trapping of blood corpuscles in this network and clot retraction might all decrease the motility of the charged particles, while variations in the effect of such processes may lead to the secondary steps and the fluctuations in the curves.

The method described may allow a convenient and accurate test for coagulation studies, particularly in connexion with the control of anticoagulant therapy where the lack of such a test may have been the obstacle to progress[20].

The help of Mr Abraham Ur and Mr Michael Gordon is acknowledged. Patents on these techniques are pending in a number of countries.

Phospholipid—Retinaldehyde Complex absorbing at 500 nm

COMPLEXES between retinaldehyde and ethanolamine phosphoglyceride (EPG)[1] have been reported by several workers[2-5], and Daemen and Bonting[4] have shown one of these (λ_{max} 450 nm in anhydrous chloroform) to be an internally protonated Schiff's base. We call this complex I. Adams[2] described an additional product, formed by combining retinaldehyde with EPG, the λ_{max} of which is 500 nm (Fig. 1). This substance, which we call complex II, is characterized here. EPG is one of the two principal phospholipids in bovine rhodopsin[6], so such complexes may well exist in the visual system and, indeed, have been identified in retinal extracts[3,5,7]. Our experimental observations indicate a direct relationship between the complex absorbing near 450 nm (I) and that absorbing at 500 nm (II). The molecular features required to form complex II are enumerated.

Addition of EPG in anhydrous chloroform–methanol to retinaldehyde in the same solvent at room temperature produces an immediate colour change characterized by a rapid increase in absorption in the 450–470 nm region. An additional increase begins at 500 nm within 30 min. Absorption in both regions continues to increase, reaching equilibrium after 3 h. We have observed this reaction using phospholipids extracted from plants, eggs or cattle retina, and combined with the following retinaldehyde isomers: all-*trans*, 9-*cis* and 13-*cis*. When these complexes are subjected to thin layer chromatography (TLC) (Fig. 1), I and II separate. Complex I has an R_F value of about 0·10 and is red–orange with absorption maxima at 458 and 340 nm. Complex II is rose in colour, has an R_F value of 0·23 and absorption maxima at 500 and 340 nm. Both substances can be eluted with chloroform–methanol (2 : 1). We confirm Daemen's finding (personal communication) that complex I is light-sensitive; when allowed to stand in room light, the red–orange colour reverts to the yellow of retinaldehyde within 1 h. In the dark the colour is stable. Complex II is much less sensitive to light, requiring several days to lose its colour. The reactants form I and II by absorbing either heat or light: mixtures of retinaldehyde and phospholipid at − 60° C show no evidence of either I or II until the mixture is exposed to light. While complex I can form at − 60° C in light, no complex II is formed unless the temperature is raised to 0° C or above. A solution allowed to react at low temperature in the light for 20 h and then warmed to room temperature produces an intense red–orange colour in a shorter space of time than a solution allowed to react at room temperature. No differences were noted between reactions in a normal atmosphere and those under nitrogen using degassed solvents.

When anhydrous methanolic HCl was added to either I or II, after elution from TLC, slight spectroscopic changes were seen only in II. The 500 nm peak shifted 3–5 nm toward the blue and the 340 nm peak about 5 nm toward the red. Addition of anhydrous methanolic HCl to I produced no changes. The addition of methanolic KOH (anhydrous) to either I or II brought about a rapid spectral change with both maxima shifting to 387 nm (presumably retinaldehyde). The initial changes in the spectrum of II, however, indicated the presence of I during the transition. In view of this, a sample of I eluted from TLC was concentrated by evaporation and on rechromatography showed the presence of II.

The only variable component of a mixture of retinaldehyde and EPG is the fatty acid content. Although equimolar samples were prepared, it seems that the percentage of fatty acid esters recovered from I is greater than from II as shown by gas liquid chromatography (GLC) (Table 1). The discrepancy suggests that II must be incompletely methylated. The methylating procedure of Morrison and Smith[8] (BF_3–methanol treatment at 100° C for 30 min) produced a brownish solution. On addition of water to hydrolyse the BF_3, the benzene layer became rose coloured, indicating that methylation was not complete. Attempts to methylate more completely were made using sodium methoxide (0·5 per cent in methanol)[9]. No improvement was noted over the results obtained with BF_3–methanol. Hydrolysis of II with methanolic KOH led to the disappearance of the rose colour; after exact neutralization with HCl, however, a rose coloured precipitate formed, presumably the potassium salt. The remaining solution contained no EPG.

Less unsaturated fatty acids were recovered from II than I (Table 1), suggesting that these are less available for methylation. The role of unsaturated fatty acids in the formation of II was examined using compounds similar to EPG from natural sources. Dipalmitoyl-L-α-cephalin (Mann Research Laboratories, New York), a completely saturated fatty acid phospholipid, produced a good yield of a II type complex; analysis of this cephalin by GLC showed, however, that it contained at least 10 per cent $C_{16:1}$ fatty acid. Distearoyl EPG was synthesized[10] and reacted with retinaldehyde: it produced a trace amount of II but GLC showed this also contained trace contaminants of 16 : 1 as well as 18 : 1 acids. Hydrogenation of the L-α-cephalin by the platinum–borohydride technique (Brown Hydroanalyser, Delmar Scientific Laboratories, Maywood, Illinois) yielded a substance which contained no unsaturated fatty acids detectable by GLC. When reacted with retinaldehyde it produced good yields of I but no II detectable by TLC. This confirms the necessity for an unsaturated fatty acid component of EPG to form II.

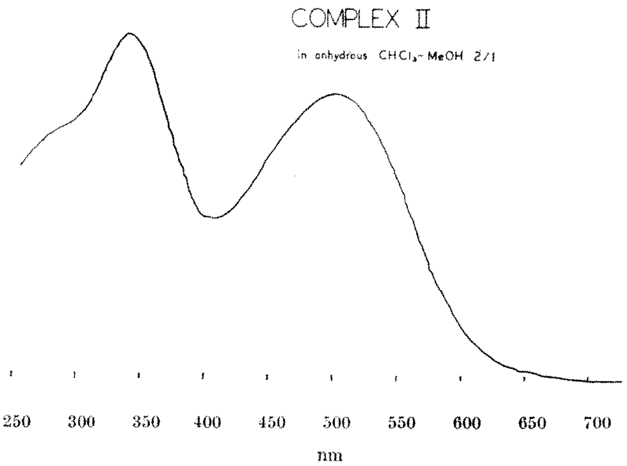

Fig. 1. Complex II was isolated on silica gel impregnated glass fibre sheets ('ITLC-SAF', Gelman Instrument Co., Ann Arbor, Michigan) by a two-dimensional system: 9 per cent methanol in chloroform followed by 2 per cent acetonitrile in chloroform. Pieces were excised and extracted with chloroform : methanol (2 : 1) for spectroscopy on a Cary 14 instrument.

The role of other molecular features of retinaldehyde which may be involved in the formation of II was examined using the vinylogous series, $C_6H_5(CH{=}CH)_nCHO$ (ref. 11). Compared with retinaldehyde, this series has (*a*) no methyl groups and (*b*) other conjugated chain lengths. For $n = 1$ to 6 we found that each compound of the series formed complex I but only those compounds with $n > 4$ formed II. The presence of methyl groups is not needed to form either I or II, even though a minimal chain length is required to form II. This leads us to characterize II as arising from I by an intramolecular interaction. The requirement for an unsaturated fatty acid residue in EPG suggests a π–π association between the isolated double bond of the unsaturated fatty acid and the retinaldehyde residue. Interactions of π orbitals (among them charge transfer processes) have been invoked by several authors[12–15] for biological systems, including rhodopsin; compounds like II are consistent with Dartnall's concept

Table 1. FATTY ACID METHYL ESTERS RECOVERED FROM HYDROLYSED EPG-RETINALDEHYDE COMPLEXES I AND II BY GLC

Preparation	Total fatty acid methyl esters	Oleic (18 : 1) / Stearic (18 : 0)		Palmitoleic (16 : 1) / Palmitic (16 : 0)	
	II/I	I	II	I	II
1	0·80	1·70	0·82	3·32	0·67
2	0·68	2·70	1·60	0·33	0·19
3	0·75	2·10	1·00	No C_{16} acids*	
4	0·86	2·40	1·30.	5·50	2·00

* Preparation using synthetic di-oleyl EPG.

The principal fatty acid methyl esters (about 80 per cent) occur in both I and II as C_{18} and C_{16} fractions. The last four columns show that in both fractions the recovery of unsaturated fatty acid methyl esters is relatively greater from I than from II.

of multiple orbital interactions[16]. Calculations of molecular orbital parameters and considerations of stereochemical relationships further confirm the spectral data and structural conclusions discussed here.

The distinctive molecular features involved in the formation of complex II are (1) the primary amino group of the EPG which, as in the case of complex I, participates in the formation of a Schiff's base with the aldehyde group of retinaldehyde; (2) the unsaturated fatty acid residue of EPG which may associate with the retinaldehyde through a π–π interaction; (3) the length of the conjugated chain of the retinaldehyde, which is at the lower limit ($n=4$) in the limited series of ω-phenyl-enals that were found to form II type substances when reacted with EPG. The lack of a specific stereochemical configuration is not important because II can be formed by at least three of the known retinaldehyde isomers.

Conformational Changes of Mitochondria associated with Uncoupling of Oxidative Phosphorylation *in vivo* and *in vitro*

BIOCHEMICAL and electron microscopical studies have revealed[1-5] that isolated mitochondria fixed in different respiratory states display characteristic changes in their ultrastructure, and it is believed that conformational modifications of the inner membrane are fundamental to energy transfer in mitochondria[1,5]. We now report the results of a study on uncoupled mitochondria in cultured chick embryo heart myoblasts fixed *in situ*, and on isolated rat liver mitochondria uncoupled *in vitro* and examined unfixed with the electron microscope.

One day old hanging drop primary cultures of myoblasts were used. Suspended in Tyrode solution the cultures showed an oxygen consumption of about 9·5 µl./mg dry weight/h and their respiration was 50–70 per cent coupled to phosphorylation, as demonstrated by oligomycin inhibition and reversal of inhibition by 2,4-dinitrophenol. The addition of uncoupling agents to the suspension caused an increase from 50 to 100 per cent of the cell respiration.

The cultures were placed in small flat chambers containing one of the following uncoupling agents dissolved in Tyrode solution; 100 µM dinitrophenol, 100 µM 4,6-dinitro-*o*-cresol, 100 µM pentachlorophenol, 100 µM dicoumarol, or 1 µM carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone (FCCP) and incubated at 38° C for 60 min. They were then fixed in 2·5 per cent glutaraldehyde in Tyrode solution for 30 min at 0° C, post-fixed in 1 per cent osmium tetroxide in Tyrode solution for 60 min at 0° C and prepared for electron microscopy as already described[6]. All procedures were strictly standardized and the mitochondria of cells under definite experimental conditions consistently had the same ultrastructural features. (For a description of mitochondria in chick embryo heart cultured myoblasts see ref. 7.)

Two orders of changes were observed in the mitochondria of the cells treated with uncouplers of oxidative phosphorylation: (1) modifications which can be considered as physiological modulations because they are seen in the cell in normal conditions; and (2) pathological changes, which consist of polymorphous modifications of shape and ultrastructure of the mitochondria that are not usually seen in normal cells. Only the former type of modifications will be described.

In all the cells, the five uncoupling agents caused the following changes in 40–70 per cent of the mitochondria: the matrix showed an increased opacity to electrons and its structure appeared more homogeneous; the limits between the inner membrane and the matrix were much less evident or even disappeared; the intracristal spaces were increased. This ultrastructural transformation of the mitochondrial inner sac seemed to be somewhat similar to that described by Hackenbrock[1] as "condensed", in isolated liver mitochondria in respiratory state 3 (as defined by Chance and Williams[8]). Further, the mitochondria were thinner and their mean diameter was from

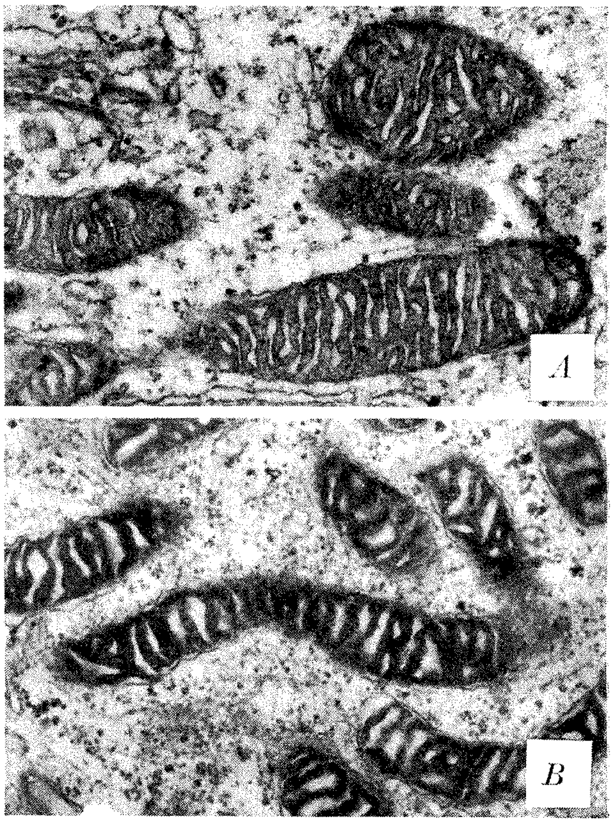

Fig. 1. *A*, Normal mitochondria in chick embryo heart myoblasts cultured *in vitro* and treated with Tyrode solution for 1 h at 38° C. × 30,000. *B*, Mitochondria in chick embryo heart myoblasts cultured *in vitro* and treated with 100 µM dicoumarol in Tyrode solution for 1 h at 38° C. Shrinking of the inner mitochondrial sac and decrease of the mitochondrial diameter. × 30,000.

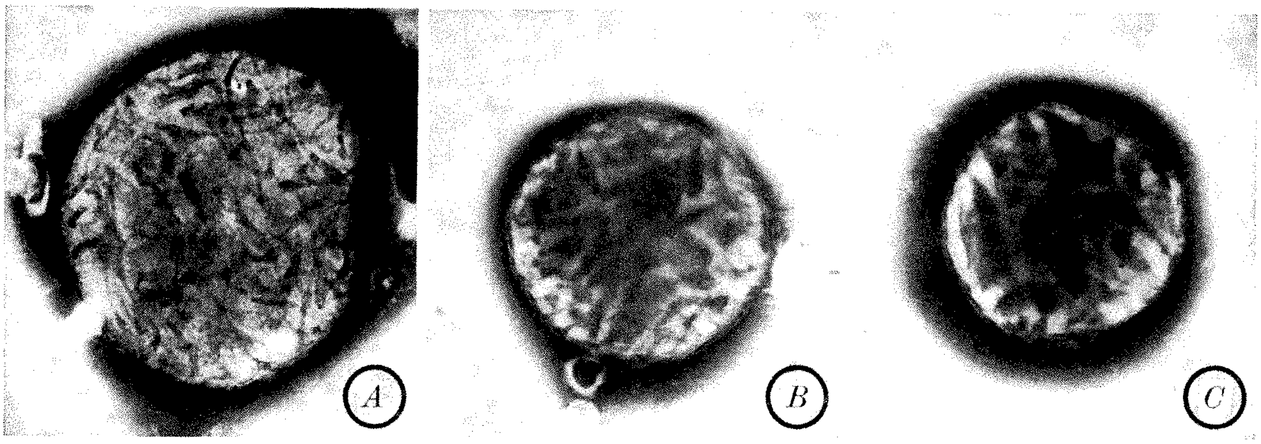

Fig. 2. Isolated rat liver mitochondria in different metabolic states and negatively stained with isotonic ammonium molybdate without preliminary fixation. *A*, Respiratory state 4. The mitochondrion appears as a large sphere embedded in the negative stain which penetrates into the intermembrane space. The inner membrane is superficially infolded. Oxygen uptake rate: low, × 60,000. *B*, Respiratory state 3. The mitochondrial volume is markedly reduced as compared with that of mitochondria in state 4. The inner membrane is deeply infolded. Oxygen uptake rate: high. × 60,000. *C*, Uncoupled respiration. The mitochondrial volume and conformation are similar to the volume and conformation of mitochondria in respiratory state 3. Oxygen uptake rate: high. × 60,000.

25 to 35 per cent diminished with respect to controls (Fig. 1 and Table 1).

Rat liver mitochondria were isolated in 0·25 M sucrose and their respiratory activities monitored with a glass electrode of the Clark type. In our electron microscopy, an improved method of negative staining[9] allowed us to avoid some of the artefacts associated with the fixation of mitochondria. Mitochondria were obtained which retained the relative volumes they have when in suspension, as indicated by a calibration curve of volume changes of mitochondria suspended in sucrose solutions of varying osmolality. The method provided us, moreover, with multiple samples of mitochondria in different respiratory states.

Table 1. EFFECT OF UNCOUPLERS OF OXIDATIVE PHOSPHORYLATION ON THE CONFORMATION AND DIAMETER OF MITOCHONDRIA IN CHICK EMBRYO HEART MYOBLASTS CULTURED *in vitro*

Uncoupling agent	Mitochondrial conformation (per cent)			Mitochondrial mean diameter (μm ± *S.E.*)
	Normal		Condensed	
Control Tyrode	91·9	(1,488)	2·6	0·32 ± 0·003 (320)
100 μM dinitrocresol	3·7	(1,825)	72·3	0·20 ± 0·003 (246)
100 μM dinitrophenol	0	(1,972)	68·4	0·24 ± 0·004 (336)
100 μM pentachlorophenol	8·4	(1,836)	60·2	0·24 ± 0·003 (305)
100 μM dicoumarol	0·1	(2,698)	60·2	0·18 ± 0·002 (490)
1 μm FCCP	14·3	(1,852)	39·6	0·24 ± 0·004 (236)

In parentheses, the number of mitochondria measured.

Mitochondria in respiratory state 4 were expanded spheres (Fig. 2*A*) and the inner sac had a conformation that corresponded to that seen in sections of liver tissue and referred to as "orthodox" conformation[1]. On addition of ADP the respiration rate increased 4–6-fold (state 3), with pyruvate–L-malate as substrate, and the mitochondria exhibited a rapid ultrastructural change: the inner sac contracted, the cristae became deeper and more convoluted and the intracristal spaces increased. The overall organization of the mitochondria thus corresponded to the "condensed" conformation[1]. As a result of this change the total mitochondrial volume decreased from 30 to 40 per cent (Table 2 and Fig. 2*B*). Similar results were obtained by using citrate, α-oxoglutarate or L-glutamate–L-malate as substrates. When 25 μM dinitrophenol was added to mitochondria in respiratory state 4, the rate of oxygen consumption increased to the level of state 3 respiration, but no phosphorylation occurred (Table 2). The uncoupled mitochondria exhibited the same change of ultrastructure and volume as the tightly coupled mitochondria (Table 2 and Fig. 2*C*). Pentachlorophenol (5 μM) elicited similar metabolic and conformational changes in the isolated rat liver mitochondria. The following evidence suggests that our results did not arise from artefacts: three kinds of chemically unrelated uncoupling agents caused similar changes in mitochondria *in vivo*; similar changes in the conformation of the inner sac were observed in mitochondria in living chick embryo heart myoblasts and in isolated rat liver mitochondria. Consistent with this suggestion, and lending further support to the conclusion that both uncoupled and tightly coupled mitochondria undergo conformational changes of a fundamentally similar nature, are the observations of the effects of uncoupling agents on light scattering changes of mitochondria *in vitro*[10]. The conformational changes observed in isolated liver mitochondria were obtained on material which had not been fixed; further, the ammonium molybdate stain does not cause serious metabolic change in phosphorylating mitochondria[11].

In conclusion: (*a*) uncoupling of respiration from phosphorylation in chick embryo heart myoblasts and in isolated rat liver mitochondria is associated with a contracted conformation of the inner mitochondrial sac formed by the inner membrane and matrix; (*b*) the shrinking of the mitochondrial inner sac is accompanied by a reduction in the total volume of the isolated rat liver mitochondria; (*c*) in isolated rat liver mitochondria the changes of conformation and volume seen in uncoupled respiration are indistinguishable from those occurring in respiratory state 3, that is, in coupled respiration.

Table 2. CONTRACTION ASSOCIATED WITH COUPLED AND UNCOUPLED RESPIRATION IN ISOLATED RAT LIVER MITOCHONDRIA

	State 4	State 3	Per cent change	*P*	25 μM DNP	Per cent change	*P*
Oxygen consumption (μl./mg protein/h)	6·2 ± 0·36	24·4 ± 0·48	+394	—	25·0 ± 0·91	+404	—
ADP : O	—	2·51 ± 0·07	—	—	0	—	—
Surface of mitochondria (μm^2)	0·51 ± 0·024	0·30 ± 0·015	−41	< 0·001	0·30 ± 0·016	−41	< 0·001

All results are given as mean ± *S.E.M.* Composition of metabolic medium for polarographic determinations: 10 mM $MgCl_2$; 100 mM NaCl; 10 mM sodium–potassium phosphate buffer, *p*H 7·4; 10 mM tris (hydroxymethyl) aminomethane-HCl buffer, *p*H 7·4; 10·5–14 mM sucrose; substrate, 1·6 mM pyruvate-0·4 mM L-malate; 2·5–4 mg mitochondrial protein per ml.; ADP 2 μmole. Final volume 3·6 ml.; temp. 25° C. 2,4-Dinitrophenol (DNP) was added to mitochondria in state 4. The mitochondria were collected for E.M. after 1 min of state 4 respiration, and after 30 s of state 3 or of uncoupled respiration. For surface determination 75 mitochondria profiles were measured for each of the three groups. Results from four experiments.

These results do not seem to be consistent with the observations of others on uncoupled mitochondria both *in vitro* and *in vivo*[1-5,12], although it should be remembered that Hackenbrock and others studied thin sections. It may be possible to clarify the discrepancies by studies on systems such as isolated mitochondrial preparations whose functioning and ultrastructure can be influenced by a variety of factors. The paucity of the information so far available and the diversity of the results obtained suggest that any generalization on the functional significance of conformational changes in mitochondria in relation to oxidative phosphorylation is at present premature.

We thank Mrs M. Gualtieri and Mr G. Mori for technical assistance. This work was supported by a grant from the Consiglio Nazionale delle Richerche.

Correlated Changes in Membrane Potential and ATP Concentrations in *Neurospora*

IN a variety of tissues, electrical events seem to be more closely associated with the active transport of ions and with metabolism than with the concentration gradients of ions *per se*. This is evident in the generation of some transepithelial potentials, for example in gastric mucosa[1]; in the hyperpolarization of sodium-loaded (and pumping) nerve and muscle cells[2-4]; and in the rapid depolarization produced by respiratory inhibitors in fungi, algae and higher plant cells[5-7]. Such phenomena may be described in terms of the electrogenic ion pump which separates charges across the cell membrane, thus generating a potential gradient along which ions will move. What is not certain, however, is whether the energy for this particular mode of ion transport is provided by ATP—which clearly drives the neutral coupled pumping of ions in many tissues[8]—or comes more directly from electron transfer, as suggested by Conway's "redox pump" hypothesis[9,10]. We have examined this question for the fungus *Neurospora*, in which the relationship between metabolic and electrical events seems particularly close.

In mature hyphae of this organism the resting membrane potential can be measured with conventional capillary microelectrodes; it is 180–200 mV (inside negative) for hyphae bathed in media containing 10–30 mM potassium, 1 mM calcium and 1–2 per cent glucose or sucrose[11]. The normal intracellular concentration of K^+ is approximately 180 mequiv/kg cell water, so that the diffusion potential for K^+ would be only 45–75 mV. The membrane potential is also rather insensitive to variations of extracellular K^+ or Na^+ concentration, and substitution of these ions by choline, *tris*-(hydroxymethyl(aminomethane, NH_4^+, or Li^+ has little effect. Metabolic inhibitors, by contrast, produce a rapid, large and reversible depolarization (Fig. 1). Within one minute of the addition of 1 mM azide to the external solution, the hyphae depolarize from 200 mV to 25 mV; repolarization on washing out the inhibitor takes place nearly as rapidly, though with a small oscillation before the membrane potential stabilizes at the control value. Separate experiments indicated that there is no significant change of membrane resistance during the rapid depolarization, although it does increase two or three-fold with maintained inhibition[5]. Because of this, we have restricted the present experiments to the period of rapid depolarization, seeking to produce the fastest possible shift of membrane potential with respiratory inhibitors and to determine which metabolic events occur with a comparable time course.

For electrical experiments, mature hyphae are grown on 'Cellophane' sheets resting on a standard medium containing 3 per cent agar[11]; after 20–28 h growth at 25° C, a 'Cellophane' square—with hyphae attached—is cut out and removed to the recording chamber. The chamber is perfused at moderate speeds (15 ml./min, chamber volume 1·7 ml.); control experiments have shown that the local concentration of inhibitor can be brought to any desired value within 0·5–1·0 s if a 20 to 25-fold higher concentration of inhibitor is suddenly introduced into the perfusing fluid. The average results from twenty such experiments, perfusing with 25 mM KCN solution (1 mM cyanide produces a maximal effect), are shown in Fig. 2.

For the first 4–5 s of inhibition, the membrane potential falls somewhat slowly and then declines exponentially. The semilogarithmic plot of the data (inset) at 5 s and beyond is fairly well fitted by a straight line with a slope of − 0·08 log unit/s, or a time constant of 5·4 s.

If the redox pump hypothesis is applicable, inhibition of electron transfer should occur with essentially the same time course as the decline of membrane potential. It is possible to examine this question fairly simply, by measuring the fluorescence of reduced pyridine nucleotides which accumulate during cyanide inhibition or anoxia. A suspension of log-phase cells[12] from a liquid culture is placed in a quartz cuvette, fitted with a pair of entry ports for syringe-needles. A constant stream of fine air bubbles (which keeps the cells suspended and oxygenated)

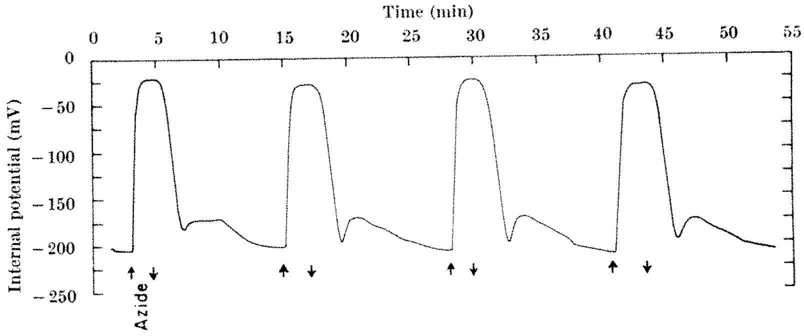

Fig. 1. Effect of respiratory inhibition on the membrane potential of *Neurospora*. Extracellular solution: 10 mM KCl–1 mM $CaCl_2$–2 per cent sucrose, throughout. At the upward arrows 1 mM NaN_3 was added, and bubbling with N_2 commenced. At the downward arrows the nitrogen and azide containing solution was washed out of the chamber.

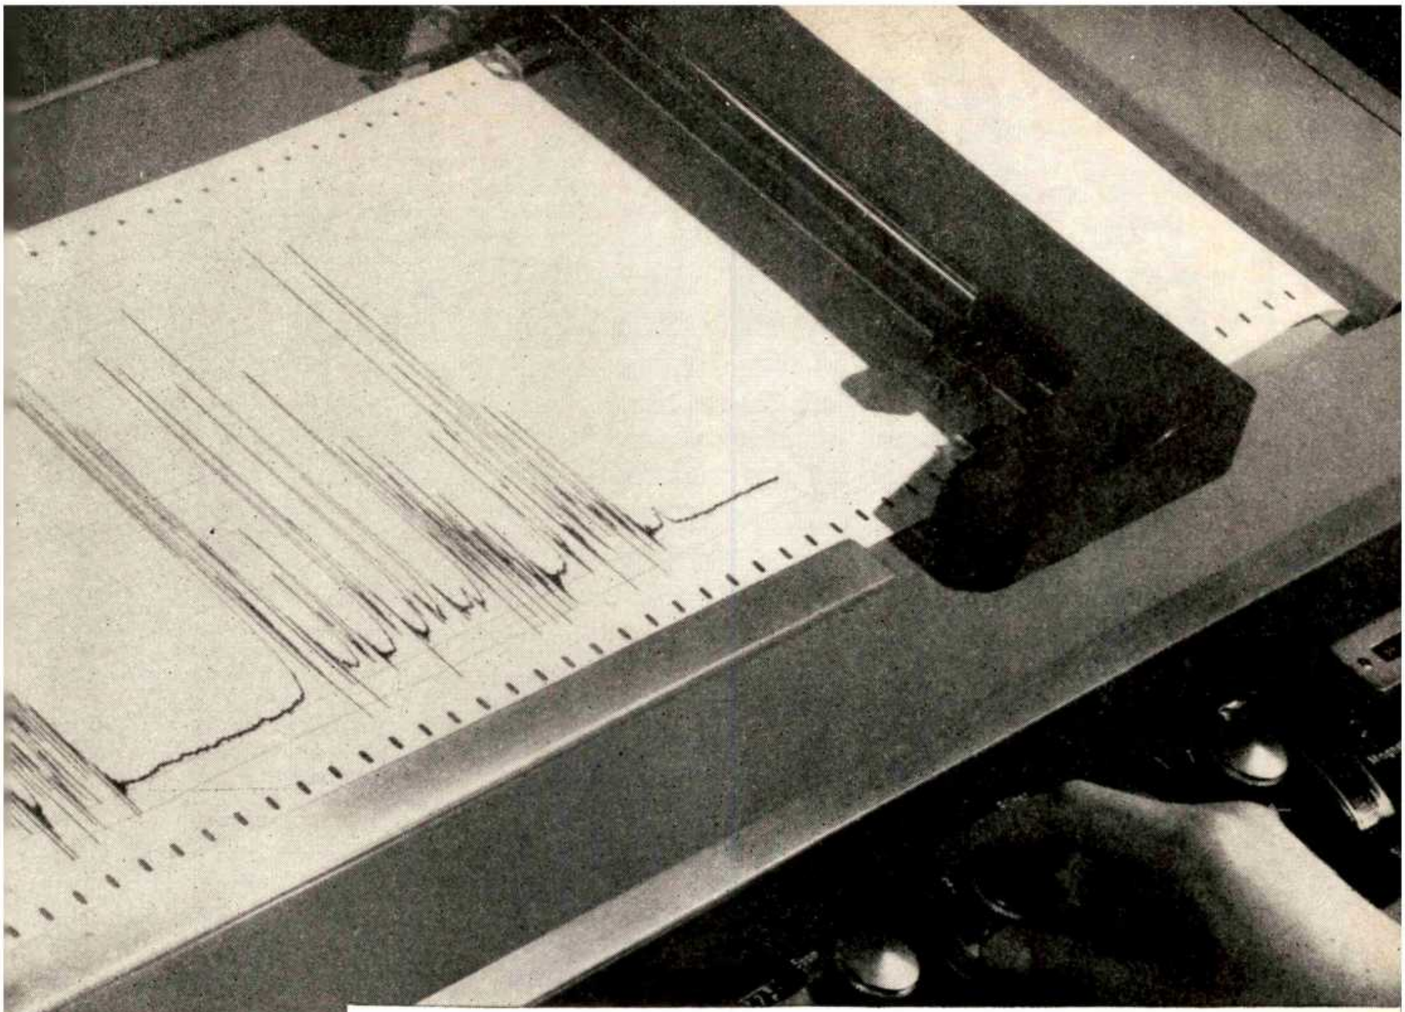

The Perkin-Elmer Model R12 is the highest-quality *routine* NMR Spectrometer in the world.

Perkin-Elmer has carried out a research programme for ten years on Nuclear Magnetic Resonance systems with permanent magnets. The Model R12 Spectrometer is the latest, outstandingly successful result. The unprecedented stability of its unique permanent magnet system ensures top performance – as a matter of easy, everyday laboratory routine. It meets all your requirements: unequalled performance and resolution stability, speed, easy routine operation – all at remarkably low-cost. It is easy to install and needs no special shielding from outside influences; it is augmented by a range of practical accessories. It is the instrument for every modern chemical laboratory.

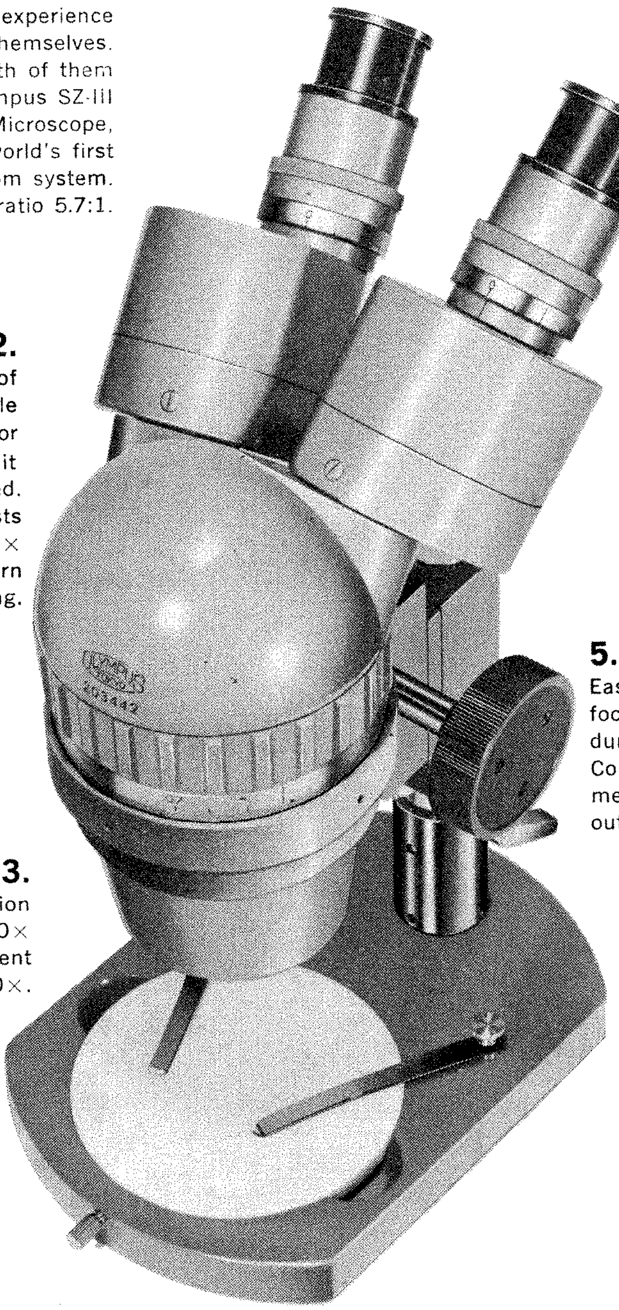
PERKIN-ELMER

You buy quality and experience in our Olympus SZ-III zoom stereo microscope

1.
Quality and experience speak for themselves. You get both of them when you buy Olympus SZ-III Zoom Stereo Microscope, the world's first with a zoom system. Zoom ratio 5.7:1.

2.
Magnification and field of view can be changed while a specimen or any magnified part of it is continuously observed. The zoom in adjusts magnification from 7× to 40× by a simple turn while observing.

3.
Continuous magnification change with ease up to 160× with objective attachment lens 2× and eyepiece G20×.



4.
For maximum comfort during prolonged observation, two types of binocular head, inclined 45° or 60°, are available for your choice. Magnification indicator ring is readable from any observer position.

5.
Easy handling without change of focus or working distance during magnification changes. Complete zooming mechanism eliminates outfocusing while zooming.

6.
Objective lens provides sharp stereoscopic images in a wide and bright field for the study of plants, the anatomy of animals, or inspection and assembly of precision parts.

and a small volume of inhibitor solution can thus be introduced during continuous recording of fluorescence. By adding excess inhibitor to the cell suspension it is possible to achieve a complete respiratory block very rapidly.

The fluorescence record from such an experiment is reproduced in Fig. 3. Because the cell suspension is turbid there is considerable high-frequency noise in the record. But this does not obscure the basic shape of the curve, which fits the sum of two exponentials. The maximal fluorescence increase—signalling maximal reduction of pyridine nucleotides—occurs 8–10 s after injection of cyanide. Partial re-oxidation then follows, perhaps because of adjustments in the glycolytic pathway. Analysis of the fluorescence curve (inset) reveals that primary reduction of pyridine nucleotides takes place with a time constant of 2·6 s, or roughly twice as rapidly as the fastest shift in membrane potential (Fig. 2). Pyridine nucleotides normally occur in great excess over other components of the respiratory electron transfer system, and Chance and Williams[14] have shown that in liver mitochondria they become reduced several-fold more slowly than either cytochromes *a*, *b* and *c*, or the flavoproteins, during the onset of anoxia. If roughly the same relationships hold in *Neurospora*, then Fig. 3 would indicate a time constant of 0·5 s for reduction of the cytochromes and 1·1 s for flavoprotein. It is therefore evident that cessation of electron transfer can occur significantly more rapidly than the decay of membrane voltage in *Neurospora*, so that the two processes can only be coupled indirectly through an energy reservoir.

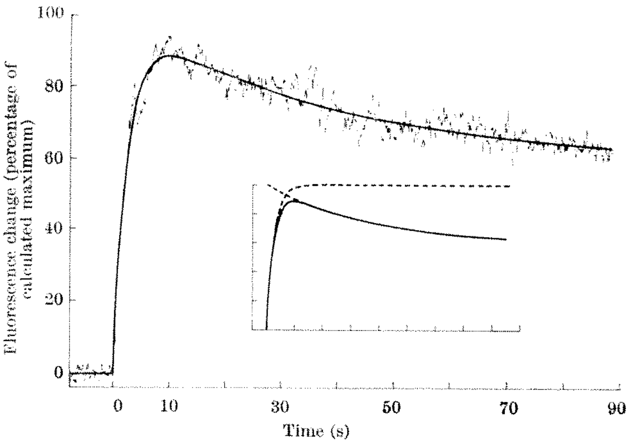

Fig. 3. Fluorescence curve of *Neurospora* during cyanide inhibition. Control medium as in Fig. 2, but with vigorous bubbling by a stream of O_2. Dry weight of cells in 2·5 ml. medium, 6·5 mg. Incident light: 360 nm; emitted light measured at 485 nm; Aminco-Bowman spectrophotofluorometer (American Instrument Co., Silver Spring). At zero time 0·2 ml. of 1 M KCN (*p*H 5·8) was injected. The smooth curve is drawn according to the equation:

$$y = 100\,(1 - e^{-t/2.67}) - 41{\cdot}4\,(1 - e^{-t/39.0})$$

where the specific numbers were obtained by a least-squares fitting procedure[13]. Inset: separation of the two exponential components.

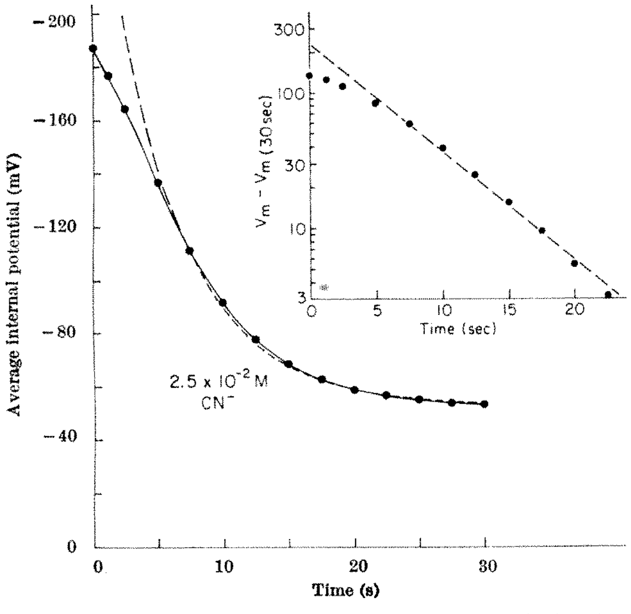

Fig. 2. Time-course of the voltage decay at the onset of cyanide inhibition. Control medium: 20 mM dimethylglutaric acid (DMG, an inert buffer; *p*H 5·8)—25 mM KOH—1 per cent glucose. At zero time, a solution of 20 mM DMG (*p*H 5·8)–25 mM KCN–1 per cent glucose was introduced. All points and the solid curve represent average membrane potentials from twenty trials on thirteen different hyphae. *S.E.* at all points was less than 6 mV. Dashed curve, obtained from Fig. 4, has a time constant of 5·4 s. Inset: semilogarithmic plot.

That this reservoir could be ATP is indicated by studies of intracellular ATP levels at the onset of cyanide or azide inhibition. A well-aerated suspension of liquid-cultured cells is harvested on a sintered glass suction filter; in the conditions used, removal of the solution (20 ml.) takes about 2 s. Just before the liquid is gone, fresh solution containing inhibitor is poured on to the cells and sucked through. At the appropriate time the cell mat is placed in petroleum ether at −70° C. By this method frozen cell mats can be obtained 3–4 s after the addition of inhibitor. The frozen mats are dried under vacuum at −20° C, weighed, pulverized and extracted with perchloric acid. The neutralized extract is assayed for ATP using the firefly luciferin–luciferase technique[15].

There is no significant difference between the effects produced by 10^{-3}, 10^{-2} (Fig. 4) and $2{\cdot}5 \times 10^{-2}$ M cyanide (not shown). Within 30 s the calculated intracellular ATP concentration, $[ATP]_i$, falls from 2·7 mM to 0·25 mM. The semilogarithmic plot of the same data (inset) gives a straight line with a slope of −0·08 log unit/s, or a time constant of 5·4 s. ATP is broken down rapidly by *Neurospora* once respiration is blocked, and this may be attributed to three factors. (1) The organism is unable to derive appreciable amounts of energy from glycolysis alone; it cannot grow in the absence of oxygen[16]. (2) It does not store energy-reserve compounds such as creatine phosphate or arginine phosphate. (3) Its normal steady-state oxygen consumption is very high, 50–75 *ul.* O_2/mg dry wt./h[5], which corresponds to approximately 0·3 mmoles/kg cell water/s (1 mg dry = 2·54 mg cell water). The P/O_2 ratio in *Neurospora* is 4 rather than 6 (E. Smith and C. W. Slayman, manuscript in preparation), apparently because this organism, like yeast[17], lacks "site I" phosphorylation. Thus the steady-state turnover of high-energy phosphate must be approximately 1·2 mmoles/kg cell water per s. The hydrolysis of two phosphate bonds per molecule in the ultimate breakdown of ATP to AMP, with a time constant of 5·4 s, corresponds to a hydrolytic rate of 0·9 mmoles/kg cell water per second—close to the calculated steady-state turnover.

The curve obtained in Fig. 4 has been superimposed (dashed lines) on the electrical data in Fig. 2 to demonstrate that after 4–5 s of inhibition the membrane potential declines in parallel with $[ATP]_i$. In other words, membrane voltage (and presumably the pumped ionic current) seems to be linearly proportional to $[ATP]_i$ at levels below 1·5 mM. At higher ATP concentrations, however, the voltage appears to saturate, so that a plot of the membrane potential against $[ATP]_i$ yields a rectangular hyperbola, as might be expected for an enzymatic process.

To a certain extent the result in *Neurospora* resembles those obtained by Durbin[18] and by Forte, Adams, and Davies[19] for gastric mucosa, where a linear relationship seems to exist between tissue ATP levels and the short-circuit current or rate of secretion of H^+. The response to respiratory inhibitors in *Neurospora* is, however, both much faster and much less complicated by cellular

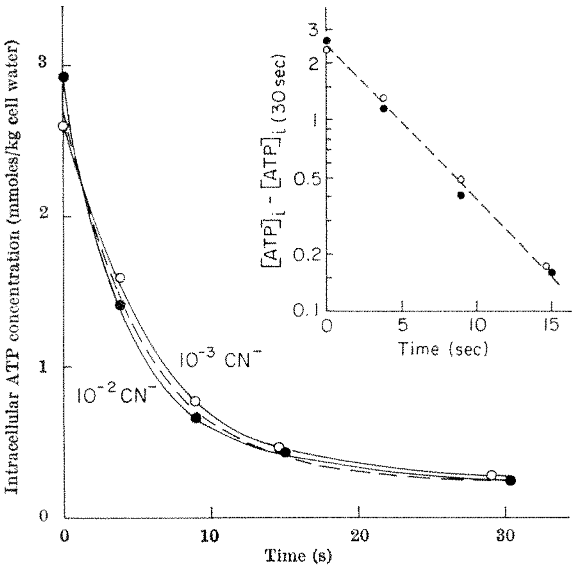

Fig. 4. Decay of intracellular ATP at the onset of cyanide inhibition. Control medium as in Fig. 2. At −2 s the cell suspension was filtered, and at zero time a buffer solution containing 1 mM (○—○) or 10 mM (●—●) KCN (*p*H 5·8) was sucked through the cell mat. Dashed curve: replot of the least-squares line from the inset. Inset: semilogarithmic plot; least-squares slope: −0·080±0·002 log unit/s; time constant: 5·4±0·2 s.

heterogeneity than in a complex tissue. On the other hand, direct measurements of ion-pump activity—like those by the short-circuit technique—are more difficult with this microorganism than with large pieces of tissue. Because we have not measured short-circuit currents and have not really controlled $[ATP]_i$ of the hyphae at will, it would be premature to conclude that ATP is in fact the direct energy source for the membrane potential. But clearly the fluorescence data require some kind of intermediary between electron transfer and the membrane potential, and the nearly exact coincidence between the rates of decay of ATP and the voltage would point to ATP.

Trypan Blue-induced Deletions in Duplication Strains of *Aspergillus nidulans*

IN the filamentous fungus *Aspergillus nidulans*, strains with a chromosome segment in duplicate (one in normal position, one translocated to another linkage group) are unstable at mitosis[1,2]. This "mitotic non-conformity" is provoked by chromosomal imbalance and initial changes of genotype are confined largely to the segments carried in duplicate[3,4]. Duplication strains, which have a characteristic morphology and reduced linear growth rate, give sectors produced by nuclei which have undergone spontaneous deletions, of variable size, from one or other duplicate segment. Sectors can almost always be scored unequivocally by their improved morphology and relative growth advantage, determined by nuclei more nearly haploid in quantity than those of the duplication parent. In suitably marked strains, loss of one or more dominant alleles gives sectors differing from the parent in conidial colour and/or nutritional requirements (Fig. 1*a*). The approximate size of each deletion, and the segment involved, can be determined by genetic analysis or sometimes

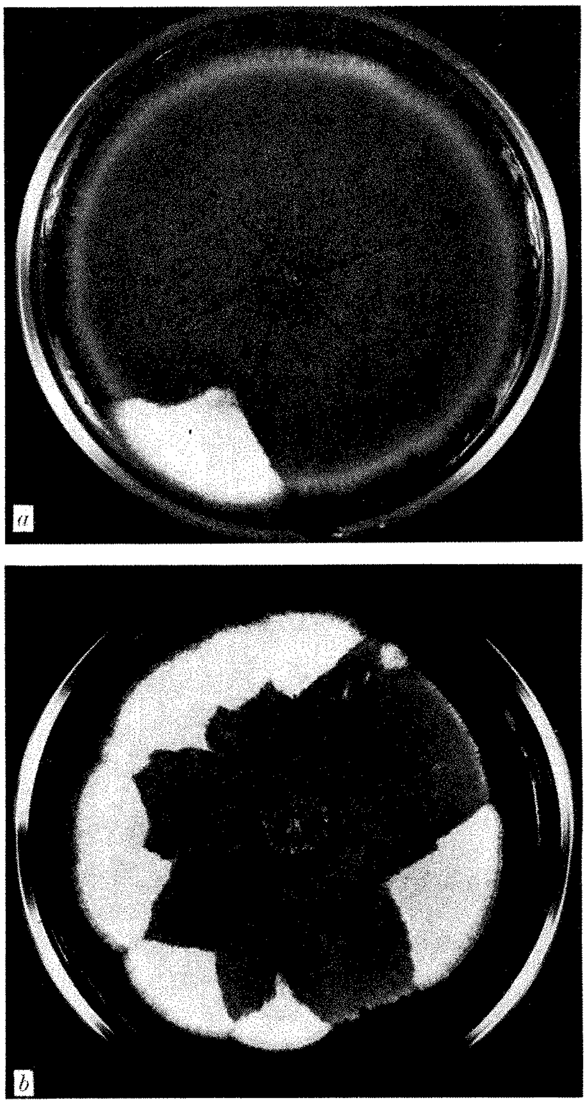

Fig. 1. Yellow sectors, produced by a duplication strain with green conidia, following deletion of the dominant y^+ allele: *a*, control after 7 days; *b*, grown on 300 μg/ml. trypan blue for 9 days.

simply by the morphology, nutritional requirements and stability or instability of the sector carrying it. This system seems to offer a simple screening test for deletion-producing agents and for any selective activity they might show towards particular chromosome regions. In addition, success in modifying sector frequency might help in elucidating the processes of mitotic non-conformity. The first attempt to induce deletions, using trypan blue (TB), has been successful.

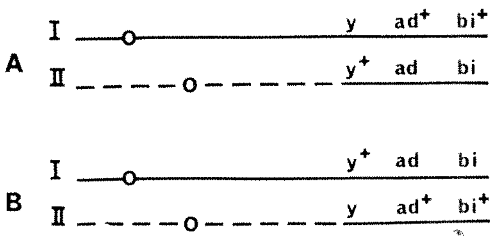

Fig. 2. Genotypes of strains used. Linkage groups I and II are shown by unbroken and broken lines respectively. The recessive, mutant alleles determined: *y*, yellow conidia, as opposed to wild-type green; *ad* and *bi*, requirement for adenine and biotin respectively.

Conidia of strain A (Fig. 2) were inoculated at the centre of 9 cm dishes of complete medium[5] containing 0 to 300 μg/ml. TB; sectors were scored after 7 days at 36° C. Plated conidia showed 100 per cent viability on all the TB concentrations used, but linear growth was significantly reduced above 50 μg/ml. ($\bar{x}_c = 7{\cdot}25$, $\bar{x}_{50\ \mu g} = 7{\cdot}01$, $t_{(70)} = 4{\cdot}0^{***}$) and was 71 per cent of the control at 300 μg/ml. ($\bar{x}_{300\ \mu g} = 5{\cdot}18$, $t_{(70)} = 41{\cdot}4^{***}$). The number of sectors per colony showed a Poisson distribution both in controls and all treatments. The Kolmogorov–Smirnov two-sample test was therefore used for all comparisons. There were slightly more yellow (20) than green (14) sectors in the forty control dishes. Although the difference was not significant in this one control series, it was consistent with general experience of the system and showed that deletions which included the y^+ allele, on the translocated segment, exceeded the sum of all other deletions. This excess of yellow sectors was generally maintained at all levels of treatment and, while TB significantly raised the frequency of yellow sectors at concentrations in excess of 50 μg/ml., only a marginal increase in the frequency of green sectors was produced at 300 μg/ml. (Table 1). Mutagenic activity at the higher TB concentrations was underestimated as a result of growth inhibition, which reduced the number of nuclei exposed to test, and by the large number of sectors which drastically reduced the proportion of the colony periphery available for further sectors. In fact, colonies grown for 9 days on 300 μg/ml. TB had a largely yellow periphery (Fig. 1*b*). This, and the dose response results, implied a preferential activity of TB on the segment carrying y^+.

Table 1. SECTORS PRODUCED BY CONTROL AND TRYPAN BLUE-TREATED COLONIES OF STRAIN *A*

TB treatment (μg/ml.)	No. of dishes	Mean No. of yellow sectors	Significance of comparison with control	Mean No. of green sectors	Significance of comparison with control
Control	40	0·50		0·35	
0·025	40	0·38	—	0·55	—
0·25	40	0·53	—	0·43	—
2·5	40	0·45	—	0·38	—
50	32	1·44	5–1 per cent	0·47	—
300	32	4·34	< 0·1 per cent	1·03	10–5 per cent

Strain B (Fig. 2), with mutant and wild-type alleles reversed between the duplicate segments, gave few spontaneous or induced yellow sectors, though it responded as sensitively to TB as did strain A. This showed that the selective activity of TB on the translocated segment of strain A was determined not by the alleles it carried but by its structural position in the genome. Many induced sectors retained some degree of the duplication morphology; they arose from only a partial deletion, preferentially from the translocated segment. The preponderance of induced yellow sectors from A and green from B could not be explained in terms of a possible advantage of normal haploid nuclei, resulting from total deletion of the translocated segment, over translocated haploids resulting from the alternative deletion. Further characterization of the sectors and an extended statistical analysis will be published later.

The translocated state of one of the homologous, duplicate segments must account for its greater susceptibility to spontaneous deletion; this can be explained tentatively in terms of a greater liability to replication error[3]. It is less easy to offer a plausible explanation for the differential action of a mutagen. Tests being made with other mutagens should show whether the differential action reflects a special property of trypan blue or whether it results frequently from the interaction of mutagens and the processes of mitotic non-conformity.

Cell Wall Thickness, Size Distribution, Refractive Index Ratio and Dry Weight Content of Living Bacteria (*Staphylococcus aureus*)

I HAVE described[1] experiments on the identification of living bacteria using their differential light scattering signatures, following a theoretical study[2] which proposed that different biochemical structures should scatter light in essentially different manners. For water suspended bacteria, the Rayleigh–Gans scattering theory[2] does indeed describe the light scattering measurements to within experimental error[3]. As a consequence of the excellent correspondence between theory and experiment, I have been able to estimate the average cell wall thickness of *Staphylococcus aureus* from light scattering data obtained from living cells suspended in water. Further, I have deduced a rather accurate characterization of the cellular size distribution, as well as a certain refractive index ratio. On the basis of the ratio the dry weight content of the cell wall and cytoplasm can be estimated. Until now there seems to have been no means[4] by which the ultrastructure of living cells might be measured directly.

Fig. 1 presents the recorded differential scattered intensity of vertically polarized 632·8 nm radiation from a viable culture of *S. aureus* (supplied and identified by Mrs Peggy Flynn, Goleta Valley Community Hospital Laboratory). The cells were grown at 37° C for six hours on heart infusion agar and then suspended in double distilled water. Under phase contrast examination they appeared spherical and predominantly single. The upper curve of Fig. 1 is approximately a five-fold amplification of the lower curve. The recordings in Fig. 1 are particularly well defined. The very deep first minimum is

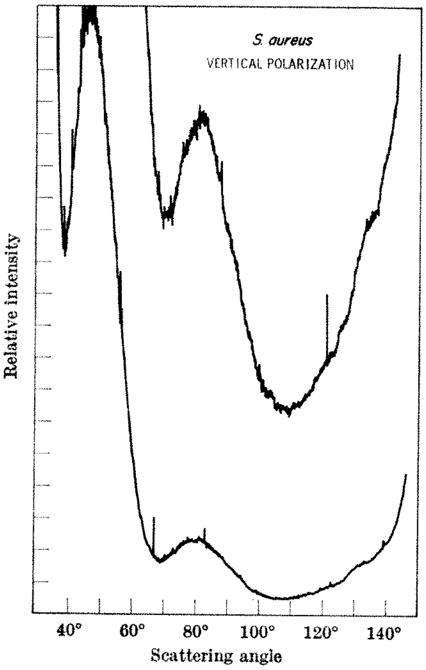

Fig. 1. Relative differential scattered intensity of vertically polarized 632·8 nm light from *S. aureus* grown on heart infusion agar at 37° C for six hours and resuspended in water. The recordings are uncorrected.

characteristic of the presence of a very narrow size distribution of cells and the standard deviation of the radius amounts to less than 20 per cent.

Fig. 2 presents a recording of the differential scattered intensity from the same cells, but illuminated by horizontally polarized radiation at 632·8 nm. Two features are of particular significance: the near vanishing of the signal at a scattering angle of 90° and the appearance of only one peak. All objects whose scattering is described by Rayleigh–Gans theory produce a scattering pattern characterized by a $\cos^2\theta$ factor for horizontally polarized radiation. The same factor is responsible for the vanishing of the second peak shown in Fig. 2, because the data can be obtained immediately by multiplying the data from Fig. 1 by $\cos^2\theta$. In other words, we learn nothing new by performing horizontally polarized light scattering measurements on Rayleigh–Gans scatterers. Thus, irrespective of the size, shape, structure or size distribution of an ensemble of Rayleigh–Gans scatterers, the intensity at 90° should always be zero. The slight positive recording shown at 90° in Fig. 2 arises from the detector's lack of perfect angular resolution. (The resolution of the detector is 2°.)

The solid curve of Fig. 3 presents the data of Fig. 1 corrected for the $\sin\theta$-foreshortening of the effective scattering volume[1,5] as seen by the detector. The two dashed curves characterize good and poor theoretical fits, respectively. Discrepancies between theory and experiment are discussed later.

The cells present in the scattering ensemble were found to be well characterized by a size variation given by

$$N(\rho) = N_0 \exp\left[-(\rho-\rho_0)^2/\Delta^2\right] \qquad (1)$$

where $\rho = kr$, r is the radius of a cell, $k = 2\pi n_0/\lambda$, n_0 is the refractive index of water at the wavelength λ of the incident radiation, N_0 is a normalization constant, Δ is the deviation in ρ about the average value ρ_0 and $N(\rho)$ is the number of cells between ρ and $\rho + d\rho$. The quantities ρ_0 and Δ must be determined experimentally. The distribution of equation (1) is quite similar to the volumetric distribution measured by Harvey and Marr[6] using a Coulter counter. A rectangular distribution has also been examined and yields essentially identical results. Indeed, for the narrow size distribution found in the present study, the exact shape chosen to characterize it is immaterial.

The data of Fig. 3 cannot be accounted for on the assumption that the cells are homogeneous or characterized by some average dielectric constant. Examination by electron microscope shows that the cells are predominantly inhomogeneous, spherically symmetric objects having a well defined cell wall. A simple model of the cells was chosen to characterize this basic type of structure, namely a spherical cell of radius r and cell wall thickness t; the refractive index of the cell wall relative to the suspending media was m_1 and that of the cytoplasm m_2. Because a distribution of sizes was present in the scattering ensemble, the fractional radius f of the cytoplasm was a useful parameter, that is, $f = (1 - t/a)$. In the Rayleigh–Gans approximation the relative intensity scattered by an ensemble of such cells is given by

$$I(\theta) = \int_0^\infty N_0 \exp\left[-(\rho-\rho_0)^2/\Delta^2\right] i(\theta,\rho)\,d\rho \qquad (2)$$

where

$$i(\theta,\rho) = [k^3 V(m_1-1)/(2\pi)]^2\,[G(u) + \beta f^3 G(fu)]^2$$

$$u = 2\rho\sin\tfrac{1}{2}\theta, \qquad \beta = (m_2 - m_1)/(m_1 - 1)$$

$$G(u) = (3/u^3)\,(\sin u - u\cos u)$$

and

$$V = \frac{4}{3}\,\pi r^3$$

A weighted least-squares fit of equation (2) to the corrected data of Fig. 3 was completed with a high-speed digital computer (CDC 6,400). The auxiliary conditions that the first four extrema occur at the experimentally measured locations (to within ±1°) were also imposed by the computer program. On this basis, the best values of the four parameters were found to be

$$\rho_0 = 6{\cdot}3 \pm 0{\cdot}3$$

$$f = 0{\cdot}82 \pm 0{\cdot}04$$

$$\Delta = 1{\cdot}05 \pm 0{\cdot}1$$

$$\beta = -0{\cdot}60 \pm 0{\cdot}15$$

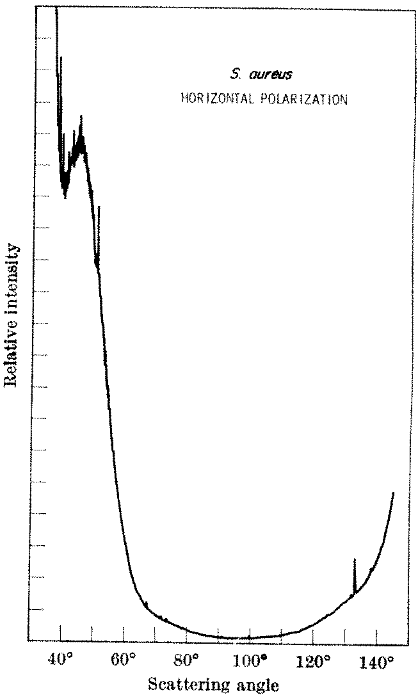

Fig. 2. Relative differential scattered intensity of horizontally polarized 632·8 nm light from the same *S. aureus* suspension as in Fig. 1.

The uncertainties in the above figures were established during the extensive numerical analysis. Both of the dashed curves of Fig. 3 have extrema at the experimentally measured positions, and both were calculated on the basis of equation (2), normalized at 47·5°. The parameters for these typical "good" and "poor" fit curves were, respectively, $kr = 6{\cdot}3$, $5{\cdot}6$; $\Delta = 1{\cdot}05$, $1{\cdot}40$; $\beta = -0{\cdot}58$, $-0{\cdot}80$; and $f = 0{\cdot}82$, $0{\cdot}84$. The slight discrepancies between the corrected data and "good" fit curves of Fig. 3 could be eliminated by more extensive numerical and theoretical analyses in which averages would be taken over the 2° angular resolution of the detector system and use would be made of the small contributions of internal reflexions at the glass interfaces of the cuvette[2,5] (Fresnel factors), the effects of cellular agglomerates (about 10 per cent of the cells were observed to be doubles) and the effects of internal structural features such as septum formation in a small fraction of the population. These corrections are unimportant here.

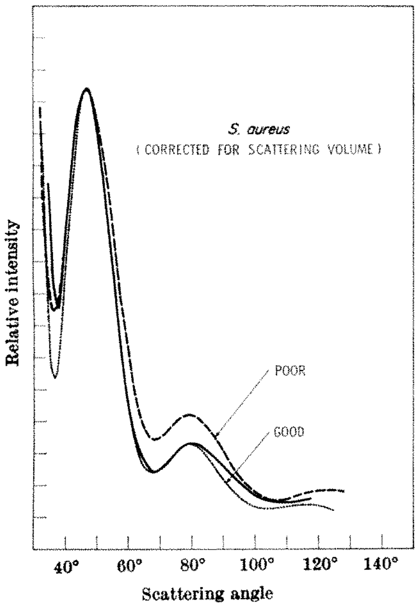

Fig. 3. The relative differential scattered intensity (solid curve) corresponding to the data of Fig. 1, but corrected for instrumentation foreshortening. The two dashed curves correspond to "good" and "poor" theoretical fits.

Specific values of cell radius, cell wall thickness and size distribution can be obtained from the above parameters. $\lambda = 632{\cdot}8$ nm and $n_0 = 1{\cdot}33$ at this wavelength, so that we have immediately

$$\text{(average radius) } r_0 = \rho_0/k = \rho_0\lambda/(2\pi n_0) = 477 \text{ nm}$$

$$\text{(average thickness) } t = (1-f)r_0 = 0{\cdot}18 \times 477 = 86 \text{ nm}$$

$$\text{(radius deviation) } \Delta/k = 79{\cdot}6 \text{ nm}$$

Electron micrographs prepared by Professor James Cronshaw suggest that for *S. aureus* grown in similar conditions the cell-wall thickness is about 18 nm and the average cell radius is about 440 nm. Salton[4] quotes a range of 10–20 nm as typical for the cell-wall thickness of *S. aureus* as deduced from electron micrographs. Although Knaysi[7] agrees in general with Salton's estimates, he does point out that ". . . in the living state [the cell wall] . . . thickness is probably several times greater. . . ." His conjecture has thus been shown to be very good. The larger cell and cell wall sizes I have deduced are consistent with the belief that cells shrink during fixation, much of the shrinkage apparently occurring in the cell wall itself.

If the cytoplasm of the cells were of the same refractive index as water, the ratio factor β would be -1. But β is greater than this value and the refractive index of the cytoplasm is, as expected, greater than 1·33. Unfortunately the refractive indices of the cell wall and cytoplasm are intimately related in the Rayleigh–Gans theory and only the ratio β may be directly determined from relative differential scattered intensity measurements. Absolute intensity measurements are particularly difficult to make, for not only must the cellular concentrations be accurately determined, but extensive calibration procedures must be introduced[5] as well.

It is not surprising that the refractive index ratio β has the greatest experimental uncertainty because, for homogeneous objects, the Rayleigh–Gans theory is essentially insensitive to scatterer refractive index. Nevertheless, if the average refractive index of the cells could be measured by another method, the data produced here might be useful in determining the refractive indices and perhaps the dry weight fractions for both cell wall and cytoplasm[8]. If, for example, the average refractive index values deduced from immersion refractometry for *B. cereus* and *B. megaterium*[9] were reasonably similar to those of *S. aureus*, the latter species would have a cytoplasm of refractive index (at 632·8 nm) 1·365 and a cell wall of index 1·42. Barer's result that the mean refractive increment is proportional to the dry weight would yield a cell wall structure consisting of about 50 g/100 ml. solid content, whereas the cytoplasm would consist of only 19·5 g/100 ml. These figures are tentative because of the large uncertainties associated with both my refractive index data and those of ref. 9; but the results are consistent and reasonable.

Work in progress on the scattering characteristics of single viable cells is expected to contribute data about the ultrastructure and chemical composition of bacteria.

Evidence for Polygenic Control of Plasmodial Fusion in *Physarum polycephalum*

THE vegetative phase of Myxomycetes (true slime moulds) is a macroscopic, multinucleate cell called a plasmodium. In many species, this structure characteristically has the capacity to migrate over solid surfaces, a feature which readily lends itself to the study of somatic compatibility. For example, when two plasmodia collide they may fuse or fail to do so, depending on whether or not they are genetically similar at certain loci[1-5]. In the two species studied so far, two somewhat different explanations have been offered. For *Didymium iridis*, a polygenic system with simple dominance at each locus has been proposed[1-3], while a one locus, multiple allelic system with no dominance has been suggested for *Physarum polycephalum*[4,5].

We have evidence that in our isolate of *P. polycephalum*, plasmodial fusion is apparently determined polygenically, as in *D. iridis*.

We used material designated Pp11, obtained from Iowa State University. The original plasmodial specimen was grown according to Camp's method[6], and within a week numerous sporangia developed. In myxomycetes, the diploid plasmodial nuclei undergo meiosis during sporangial formation, and each mature spore possesses a single haploid nucleus. When a spore germinates, it gives rise to a single uninucleate, haploid amoeba which, if isolated, can give rise to a clonal population of several million cells. Twenty-one clones were obtained and subsequently crossed with sibling testers to determine their mating types. Twelve were found to be of one mating type and seven of the other, while two could not be classified with certainty. No attempt was made to determine whether these mating types were duplicates of those described by Dee[7]. Fertile crosses made on half strength corn meal agar yielded macroscopic plasmodia in 5–10 days. These were fed sterile 'Quaker' oats until they covered most of the agar surface in 15 × 100 mm Petri dishes. Transfers and new feedings were repeated at weekly intervals.

To test for compatibility, blocks of agar containing vigorous pieces of plasmodia from two different crosses were placed side by side on the surface of 2 per cent water agar. When the plasmodia collided they were examined with a dissecting microscope, using sub-stage lighting and magnifications up to × 120. Scoring for fusion or non-fusion has been described and illustrated in detail elsewhere[1,3,4].

Table 1. SEVEN PLASMODIA TESTED FOR FUSION IN ALL DIFFERENT PAIRED COMBINATIONS

	3·5	1·3	P	5·11	11·21	1·17	1·4
3·5		–	–	+	–	–	–
1·3			–	–	–	–	–
P				–	–	+	–
5·11					–	–	–
11·21						–	+
1·17							–
1·4							

+ Fusion; –, non-fusion. All tests were made at least twice.

Results were obtained by testing the original parental plasmodium obtained from a sclerotium, and ten plasmodia derived from clonal crosses. In one experiment, seven of these plasmodia were tested in all combinations, taking two at a time (Table 1). P indicates parental, whereas two numbers separated by a dot indicate plasmodia obtained by crossing two F_1 clones; that is, clones 1 × 3. The pattern of fusion and non-fusion shown in Table 1 makes it possible to assign these plasmodia to four classes: (*a*) 3·5 and 5·11; (*b*) 1·3; (*c*) 1·17 and P; (*d*) 1·4 and 11·21. These data are not consistent with a one locus, multiple allelic compatibility system. Based on the one locus hypothesis, the parental plasmodium could carry no more than two fusion alleles; for example, F_1 F_1, F_2 F_2 or F_1 F_2. Our results show that 1·3, 1·4 and 1·17 belong to three different classes. Assuming that clone 1 carries a given allele, F_1, then clones 3, 4 and 17 could carry among them, at most, the F_1 and F_2 alleles.

In another experiment, four plasmodia (1·3, 1·4, 1·17 and 3·5) were used as testers to determine whether four additional F_1 plasmodia (11·25, 11·26, 17·18 and 5·17) belonged to new fusion classes (Table 2). These results show that only one of these, 5·17, corresponds to an established class. None of the remaining three fused when tested in all possible pairwise combinations. Thus the ten F_1 plasmodia tested were distributed among seven fusion classes. These data argue strongly against a one locus control system. According to this hypothesis, fusion occurs between plasmodia which have identical genotypes at the plasmodial compatibility locus[4,5]. For example, according to the one locus hypothesis, from the fusion of 1·17 and 5·17, we would conclude that clones 1 and 5 are identical at the compatibility locus. Accordingly the fusion of 3·5 and 5·11 indicates that clones 3 and 11 are identical at this locus. If the compatibility genotypes of clones 1 and 5 are identical, and so are those of clones 3 and 11, then fusion should occur between 1·3 and 5·11; however, no fusion was observed. These results cannot be explained by the one locus hypothesis. Furthermore, the fusion of 1·17 and 5·17 and the failure of 1·3 and 3·5 to fuse indicate the existence of dominance for at least one fusion locus.

Table 2. FOUR TESTERS (1·3, 1·4, 1·17 and 3·5) PAIRED IN ALL COMBINATIONS WITH FOUR F_1 PLASMODIA

	11·25	11·26	17·18	5·17
1·3	–	–	–	–
1·4	–	–	–	–
1·17	–	–	–	+
3·5	–	–	–	–

+, Fusion; –, non-fusion. All tests were made at least twice.

It is obvious that the myxomycetes provide excellent material for the study of the genetic control of somatic compatibility. These preliminary data about *P. polycephalum*, an organism used in many kinds of research[8,9], will be followed soon by a more extensive account. This is part of an expanding programme of study of plasmodial compatibility[1–3,10] started several years ago[11]. It will be interesting to find out whether various species have different genetic systems for the control of fusion, and whether different isolates of the same species vary in this characteristic. Recent work[4,5] on *P. polycephalum*, when compared with that described here, suggests strain differences. Alternatively, it should be pointed out that earlier data about this species fit a polygenic system almost as well as a one locus system.

This work was supported in part by grants from the University of Washington Graduate School Research Fund and a US National Science Foundation grant. We thank Miss Mina Ossiander for technical assistance.

Plant Protoplasts for Use in Somatic Cell Hybridization

SOMATIC cell hybridization is a potentially useful technique for the introduction of genetic variability into plant species. One proposed method involves fusion of plant protoplasts (which is a cell lacking its wall—defined here on the basis of light microscope examination) to form a hybrid cell which can be induced to form a plant[1]. Plant protoplasts produced by the use of crude, commercial lytic enzymes are not always healthy (as defined by consideration of factors such as cytoplasmic streaming, presence of cytoplasmic strands and position of the nucleus within the cell, in relation to survival time)[2,3]. Peroxidase[2], basic proteins[3] and ribonuclease[4] have been implicated as possible deleterious agents. The use of purified enzymes offers a more rigorously defined system for obtaining healthy protoplasts. We have used purified preparations of cellulase (EC 3.2.1.4), pectate lyase (EC 4.2.99.3) and endopolygalacturonase (EC 3.2.1.15) to prepare protoplasts from a range of plant cell suspension cultures. We have also prepared inducible streptomycete enzymes lytic towards plant cell walls.

Plant suspension cultures were grown in defined conditions[5]. Semi-purified pectinases included pectate lyase prepared from 'Pectinol 59L' (Rohm and Haas, Philadelphia)[6] and endopolygalacturonase from *Saccharomyces fragilis* C351[7]. We obtained electrophoretically purified *Trichoderma viride* hydrocellulase with high C_1 activity[8] from Miles Laboratories, Elkhart, Indiana. Polyacrylamide gel electrophoresis at *p*H 8·9 showed that each final enzyme preparation had a major and several minor components. The enzymes were sterilized by filtration and used in the concentrations given in Table 1. The final concentration of sorbitol in all experiments was 0·35 M. Protoplasts were produced as follows. Cells were washed and resuspended in 0·01 M sodium citrate (*p*H 5·5) containing 0·35 M sorbitol. The cell suspension (10 µl.) was then incubated with glycosidases in hanging drops (40 µl.) using depression slides. Mineral oil around the coverslip prevented evaporation. Microscopic observations were made during 24 h. Hydrocellulase alone forms protoplasts from *Glycine max* L., *Meliotus alba* Desr. variety 'Arctic' and *Linum usitatissimum* L. while pectinases had no further effect (Table 1)—when they were added the resulting protoplasts were less healthy. This was probably because of the toxic nature of extraneous substances in the semi-purified pectinases. Power and Cocking[9] obtained excellent yields of protoplasts when they used mixtures of crude commercial cellulases and pectinases against tobacco leaves.

Table 1. PROTOPLAST FORMATION USING COMBINATIONS OF HYDROCELLULASE AND PECTINASE

Cell cultures	Hydro-cellulase*	Hydro-cellulase + pectate lyase †	Hydro-cellulase + endopoly-galacturonase ‡	Hydrocellulase + pectate lyase + endopoly-galacturonase
Glycine max L.	+	+	+	+
Rosa sp. variety 'Sceptre'	–	–	–	–
Triticum monococcum L.	–	–	–	–
Haplopappus gracilis (Nutz) Gray	–	–	–	–

Linum usitatissimum L.	+	+	+	+

Culture conditions are given in ref. 5. Negative results were obtained using endopolygalacturonase and pectate lyase either singly or in combination.

* Final concentration was 0·026 U/40 µl. (A unit is defined as the release of 1 µmole of monosaccharide equivalent per minute from carboxymethyl cellulose[2], pectin[3] and polygalacturonic acid[4] respectively.)

† Final concentration was 0·21 U/40 µl.

‡ Final concentration was 0·42 U/40 µl.

+ +, 5–20 per cent protoplasts in 3 h.

+, 5 per cent protoplasts in 3 h.

–, No protoplasts in 24 h.

Cell walls of the plant cultures were prepared by grinding cells with glass beads (120 µm) in an ice-cooled 'Omnimixer' at high speed. Crude wall preparations were boiled, treated with purified α-amylase for 2 days in the presence of toluene, separated from the glass beads and fine particulate materials by differential centrifugation and then washed exhaustively with water and freeze dried. The gross sugar composition was determined by analysing the products of acid hydrolysis by paper chromatography[5]. Pectin hydrolysates were chromatographed using ethyl acetate–pyridine–acetic acid–water (5 : 5 : 1 : 3) and identified with naphthoresorcinol/phosphoric acid reagent[10]. Composite results are presented in Table 2. Cell walls of each species contained substantial proportions of cellulose and pectin. *Haplopappus gracilis* (Nutz) Gray, *Rosa* sp. var. 'Sceptre' and *Triticum monococcum* L. also had substantial amounts of arabinose, galactose and xylose. There is a fair degree of correlation between protoplast forming ability (Table 1) and cell wall composition (Table 2)—cellulase on its own formed protoplasts from species with cell walls containing the least amounts of arabinose, galactose and xylose. There were, however, greater amounts of alkali soluble polysaccharides in *M. alba* cell (51 per cent) than in *H. gracilis* cell walls (26 per cent). The relative amount of cellulase used (final concentration 0·058 per cent) (Table 1), is much less than that used by others (2–5 per cent)[3,9,11]. The specific activity, 1·13, of this purified cellulase was little higher than that of a crude commercial cellulase 0·58 ('Onozuka SS' cellulase, All Japan Biochemicals Ltd, Nishiomiya) when assayed by following the hydrolysis of carboxymethyl cellulose reductiometrically[12]. The relatively small amounts of purified cellulase capable of producing plant protoplasts may be a reflexion of its high C_1 activity[8].

We do not know why cellulase alone or in combination with pectinases did not form protoplasts from *H. gracilis*, *Rosa* sp. and *T. monococcum*. Possibly the action of the yeast endopolygalacturonase or fungal pectate lyase could require the prior action of an arabino-furanosidase. These pectinases act respectively on low and highly esterified pectins. Though pectinases promote disaggregation of plant tissue from various species[13] and aid in cell wall degradation[9,14], they are not essential for the production of protoplasts from cells of *G. max*, *L. usitatissimum* and *M. alba*. Lipases and proteases do not seem to be essential in the formation of fungal protoplasts[12]. Presumably specific arabinose, galactose or xylose-containing hemicelluloses of the cell walls of the former species either prevented the action of cellulase against essential structural cellulose components by a physical masking action, or themselves gave sufficient structural support to the walls to prevent the formation of protoplasts. Some other factor may be necessary to initiate lysis[14].

Possible sources of other cell wall lytic enzymes (for example, hemicellulases) include (i) crude commercial enzymes and (ii) inducible enzymes produced by culturing a lytic organism in the presence of cell walls. The latter can be used to prepare specific glycosidases, active towards single plant species. We used *Streptomyces* sp. 0143[12] for the preparation of enzymes lytic towards *H. gracilis*. The fungus was grown on a chemically defined medium[12] with 0·3 per cent dry cells as a source of carbohydrate. Extracellular enzymes produced after 4 days were concentrated, desalted and tested for effectiveness in producing protoplasts, which were obtained from *H. gracilis* cells when incubated with the induced enzymes. Analyses of enzyme hydrolysates from *Haplopappus* cell walls yielded arabinose, fucose, glucose and an unidentified uronic acid. The purification of hemicellulases demonstrated to be present will be attempted when the hemicellulose components of the cell walls have been analysed structurally.

The fact that a single enzyme can be used to produce protoplasts from certain plants is encouraging in the search for a rigorously defined "protoplast-hybridization" methodology. The production of specific inducible lytic enzymes may also help in attaining this objective. We have observed regeneration of cell walls on protoplasts using commercial enzymes as others have[11,15,16], but conclusive evidence of complete cell regeneration must await the demonstration of both nuclear and cellular division.

We thank Dr T. Eriksson, University of Uppsala, for a culture of *Haplopappus gracilis*. We also thank L. Harmon and T. S. Sieben for technical assistance.

Biological Control of *Pistia stratiotes* L. in Western State, Nigeria

Pistia stratiotes L. is a free-floating water-weed, common on many waters in West Africa. It is capable of rapid vegetative reproduction by offshoots, and concern has been expressed over a possible infestation of the lake behind the newly closed Kainji dam on the River Niger in Nigeria where the plant is now accumulating. Our discovery of the cause of a die-back of this plant which occurs annually on enclosed and permanent waters in the Ibadan area of Western State, Nigeria, offers some hope, however, that the plant could be controlled biologically on Kainji Lake.

Systematic field observations from October 1967 to January 1969, coupled with results from experiments on the growth pattern of the plant, showed that the die-back in the Ibadan area was associated with a virus infection which reached epidemic proportions during the wet season. The sequence of events observed during this period is believed to be typical of the annual die-back.

Infected plants were rare during the dry season (November–March) and the beginning of the wet season. The infection started spreading rapidly during May, some time after the beginning of the rains, and continued until mid-July by which time no symptomless plants could be found on any of the waters of the Ibadan area. By September most of the infected plants had died, although some were still alive. During October, at the end of the rains, a few symptomless plants reappeared and were responsible for the build-up of the dry season populations.

Infected plants were readily identifiable in the field by the deep yellowing and brittle nature of their lowermost leaves and by their less vigorous growth. The infection seems to have been spread by the widely distributed aphid, *Rhopalosiphum nymphaeae* L., which occurred on *Pistia* in small numbers during the dry season but greatly increased in numbers during the wet season when the winged forms were also dispersing. Transmission of the disease by this insect has been demonstrated experimentally in the greenhouse.

The seasonal differences in the spread and effects of the disease were attributable to the population changes of the aphid coinciding with changes in climatic conditions and, perhaps more important, with changes in the nutrient status of the water. When the aphid population was enlarging and dispersing during the early rains, growing conditions for the plant were less favourable because of the cool, overcast conditions and the dilution of the nutrients in the water by the frequent heavy rains, and plants began to show signs of mineral deficiency. In these conditions spread of the infection was rapid and the weakened plants succumbed readily to the disease. During the dry season, when the aphid population was much reduced and relatively sedentary, growing conditions were better with less overcast skies and the nutrient status of the water reached its highest levels. Changes in these conditions have been shown experimentally to affect survival and growth rates of infected plants.

The symptomless winter populations are believed to have been derived from infected plants rather than seed. There is evidence that the spread of the virus to the offshoots is relatively slow and, in the better growing conditions of the dry season, the rate of vegetative propagation outstrips infection; but here we do not yet known enough.

A somewhat similar cyclical die-back of *Salvinia auriulata* Aublet, associated with a saprophytic *Alternaria* sp. and a parasitic *Spicariopsis* sp., has been described from Lake Kariba[1]. In this case circumstantial evidence suggested that the degeneration was chiefly caused by physiological–ecological factors which predisposed the plants to fungal infection.

The infection of *Pistia* does not bring complete control, only a dramatic cut-back of the population during the unfavourable conditions of the wet season. Observations suggest that the infection may be widespread in Western State, Nigeria, and, although we do not know whether it occurs elsewhere, conditions seem favourable for its existence throughout much of the forest region of West Africa. It may have caused the partial disappearance of *Pistia* from the Volta Lake in Ghana, after an initial build-up when the dam was closed; in time, it may also affect the accumulation of *Pistia* behind the newly closed Kainji dam. The climate of the Kainji area, however, is drier than that of Ibadan, and the wet season is shorter, so that the infection may consequently be less effective. If no infection appears at Kainji it would, of course, be advisable to introduce infected plants into the population to see whether some measure of control would result.

Symbiotic Emergence of Metazoans

It has been assumed that differentiation during embryonic development is based on the regulation of gene activities. The differentiation of each cell, then, results from the activity of certain genes and the inactivity of others. Practically all theories of embryonic development rely on this assumption (see Markert[1]). It is evident that different genes are active in different cells (that is to say, haemoglobin genes in erythroblasts, thyroglobulin genes in thyroid cells, myosin genes in muscle cells). But the precise programming of cells containing thousands of genes still fails to explain the regular embryonic development, which depends not only on cellular differentiation but on precise cell divisions, cell and tissue movements, cell interactions and even cell death. Moreover, embryonic development is flexible enough to respond to injury, from the formation of complete identical twins to the fusion of two organs to form a single one.

It is perhaps necessary to explore hypotheses of embryonic development that are not restricted to the processes of cell regulation at the level of gene transcription. It is known that the instructions for embryonic development are present in the unfertilized egg. These instructions encompass all levels of biological organization, however, and, furthermore, they have changed and evolved during the evolution of metazoans. It is often assumed that metazoans evolved directly from one line of unicellular organisms. In this report, I explore the possibility that metazoans were the inevitable result of the intracellular symbiosis of many unicellular (prokaryotic and eukaryotic) organisms when they could no longer survive as single cells; metazoans were formed when the daughter cells remained together and formed intercellular symbionts. The theory[2,3] and the experimental evidence[4-6] for the occurrence of intracellular symbiosis during the evolution of eukaryotic cells have been reviewed before. Furthermore, the intracellular union of two or more cells is easily achieved in tissue cultures[7].

An intracellular symbiont could have had a better chance of surviving because it would be more adaptable to environmental or nutritional changes than any of its parent cells. It is also probable that not all the genetic information would be used during any one life cycle, but that some would be maintained and used only when required for survival. The genetic system resulting from intracellular symbiosis would provide variability for survival under changing conditions, but it also would be under pressure to lose redundant genetic information. The result could be the maintenance of integrated genetic networks, capable of switching on or off in response to external stimuli. Survival pressures would probably work towards the stabilization of such genetic networks so that their functions would be more and more mutually exclusive. The organisms would, however, remain flexible enough to utilize the different genetic networks at different times. Models of how the integrated activation of batteries of genes can produce different states of cellular differentiation have been made[8]. For survival, any one of the various states of differentiation could be switched on or off in response to the environmental requirements. For example, the amoebo-flagellate transformations in protozoans[9] may reflect the pre-existence of such intracellular symbiotic forms; at present, they can switch and use mostly the genes of one or the other of the original partners depending on the environmental requirements.

Under pressure to express simultaneously more than one of the many possible differentiated states, the descendants of one cell could have remained together, and evolved into primitive metazoans. Such a primitive metazoan would be an intercellular symbiont with the multiplicity of its genetic information expressed simultaneously, but in different cells. All the advantages of the original intracellular symbiont, that is, its capability of expressing different genetic networks at different times, were now transferred to the new organism. But now there would be an added advantage; the capability of simultaneous expression in one multicellular organism.

Then, during the further evolution of the metazoan, the successive differentiated states could be triggered by signals produced from the neighbouring cells rather than by changes in the environment. The result would be stabilization of the morphology of the symbiont. As in all symbiotic relationships, the interdependence of the partners would result in the loss of redundant functions and in increased cooperation. This was probably more apparent in the formation of the primitive tissues and organs. For example, the primitive gut was a cavity where cells cooperatively digested food by extracellular secretions. Other cells in the symbiont survived by absorbing the nutriment without a need for proteolytic enzymes. The processes of early embryonic development are similar in all metazoans. First, there is a period of rapid cell cleavage, followed by a time of cellular movement and interaction between the cells in the different regions. Tissue and cellular differentiation then begins in various regions. The hypothetical primitive intracellular symbiont as it evolved into an intercellular symbiont would have gone through these same processes.

Any hypothesis of embryonic development must explain the origin and the evolution of the developmental processes that lead to cell differentiation, besides explaining the genetic regulation which is commonly believed to account for cell differentiation. The hypothesis of intracellular–intercellular symbiosis provides an explanation of the origin of metazoans which emphasizes the survival value of the developmental processes. The origin of metazoans through intracellular and intercellular symbiosis may be illustrated by considering a simple hypothetical example (Fig. 1). For illustration, both exaggeration and simplification are used, thus diminishing the probability of such events actually occurring. Although proof of this theory must await the design of new experiments, some experimental evidence can be explained in its light.

The large amounts and the different kinds of genetic messages required for the transition from unicellular to multicellular life are the result of intracellular symbiosis, and not of mutation alone. On this basis, metazoan cells would have much larger amounts of DNA than unicellular organisms, as indeed seems to be the case[9,10]. And, because all unicellular organisms carry on much the same basic life processes, large amounts of redundant DNA would also result from intracellular symbiosis and be found in metazoans[11].

A loss of redundant DNA would also be expected, however, because the specialization of the intercellular symbiont would depend on the interdependence of its cells. We should therefore find that, in some cases, organisms considered more primitive in the evolutionary scale could have more DNA than organisms considered more advanced. For example, the lung fish contains seventeen times more DNA than the frog, and the frog has twice the amount of DNA as has the mouse[12].

If the survival of the intercellular symbiont depended on the cooperative function of neighbouring cells, then survival pressures dictated not only for the morphogenetic movements responsible for the establishment of these relationships, but also for the complete morphology attained by an organism. In this light, embryonic regulation (twinning of organs and embryos, and the organ fusion, reaggregation and formation of complete embryos from dispersed cells) may be considered an attempt of the components of the symbiont to attain the relationship that provides for maximum survival capacity.

Initially, any one cell could have given rise to a complete individual and the primitive metazoan could have reproduced by liberating a few cells. Later, however, as all the other cells in the organism specialized, so did the egg cells. They were provided not only with yolk but also "masked" messenger RNA (ref. 13) to carry out cellular proliferation

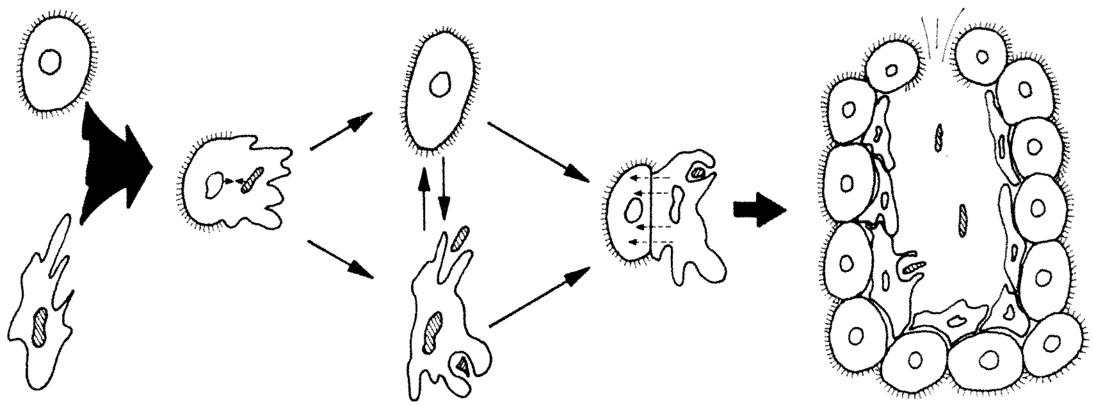

Fig. 1. If an amoeboid is considered to unite with a ciliated organism, the resultant symbiont, by being able to switch and use the genetic networks of either parent, would be at a survival advantage. For example, if the nutriment was largely particulate, the amoeboid form would be more advantageous. On the other hand, in the presence of soluble nutriments and predators, the ciliated organism would have a better chance to survive. Under survival pressures, there would be the development of mechanism for detecting changes in the environment and the capacity to switch on the appropriate genetic networks. As these mechanisms specialized, there would be the mutual exclusion of genes other than those required for a specific environment. The increased genetic information in the symbiont would also make the establishment of other morphologies possible; however, for illustrative purposes, the two extreme morphologies of the symbiotic partners are shown. As suggested in the text, the metazoan state would be established when environmental requirements made it necessary to have more than one of the differentiated cell types. In the example here, this would probably be an environment with particulate food and many predators. The formation of tissues would have resulted from further specialization and interdependence between partners.

in order to speed up the attainment of the multicellular state. Under the suggested evolutionary scheme, fertilization, which is a specialized form of intracellular symbiosis, may be considered the recapitulation of the ancestral stimulus for the emergence of metazoan life.

Are Genetic Correlations and Environmental Correlations Correlated?

CORRELATIONS between different characters measured on individuals of a population have both genetic and environmental causes. In an extensive genetic analysis of the open-field behaviour of mice, which is a widely used index of "emotionality", we have found that genetic and corresponding environmental patterns of association among pairs of characters are similar. We suggest that this relationship may frequently occur in nature and may account for the failure of recent attempts to obtain maximally and minimally heritable factor scores by multivariate analysis.

In quantitative genetic theory[1], the observed phenotypic value of a character measured on an individual may be partitioned as

$$P_x = A_x + E_x \qquad (1)$$

where P_x is the phenotypic value, A_x is the additive genetic value and E_x is the deviation resulting from both environmental influences and non-additive gene effects. When two characters are measured on individuals from a segregating (non-isogenic) population and thus partitioned, the correlation between the observed phenotypic values may be expressed as

$$r_{Pxy} = h_x h_y r_{Axy} + e_x e_y r_{Exy} \qquad (2)$$

where r_{Pxy} is the phenotypic correlation, r_{Axy} is the genetic correlation (that is, the correlation between the additive genetic values for the two characters), r_{Exy} is the corresponding environmental (plus non-additive genetic) correlation, h is the square root of the heritability of the indicated character ($h^2 = V_A / V_P$, where V_A and V_P are the variances of the additive genetic and phenotypic values), and $e = (1 - h^2)^{1/2}$. From equation (2), when characters are measured on individuals from an isogenic population the observed phenotypic correlation is a direct estimate of r_E, because V_A and, hence, h^2 are zero. Non-additive genetic deviations within isogenic populations must also be zero; thus, when environmental correlations are estimated from isogenic populations, the resulting estimates will be based only on associations between environmental deviations.

As part of a genetic analysis of open-field behavioural characters of mice[2,3], data were obtained from 2,641 subjects including members of two inbred strains (BALB/cJ and C56Bl/6J) and their derived F_1, backcross, F_2 and F_3 generations. Individuals were tested in a brightly lit open field for three minutes on each of two consecutive days at 40 ± 5 days of age. Walls and floor of the field were constructed of white, painted 'Plexiglas'. Two sets of five light sources were beamed through holes and red filters on each of two adjacent sides of the field to photoconductive cells on the opposite side, effectively dividing the floor into thirty-six squares, 6 × 6 inches each. The number of light beams interrupted during each test was automatically recorded on counters and the number of faecal boluses deposited by each subject was counted at the conclusion of each test. The resulting daily activity scores (number of light beams interrupted) and defaecation scores (number of faecal boluses) were subjected to square root transformations. Our methods are discussed in more detail elsewhere[2].

Phenotypic correlations among the single-day behavioural scores are presented for each strain and derived generation in Table 1. These values were obtained from unweighted means of correlations calculated separately by sex and, where reciprocal crosses were involved (F_1, B_1, B_2 and F_2), by mating class. (This method of pooling was found to yield values very similar to those obtained by pooling corrected sums of squares and cross products across subclasses.) As expected, activity on days one and two (A_1A_2) and defaecation on days one and two (D_1D_2) are each positively correlated for all generations. In contrast, all correlations between single-day activity and defaecation scores are negative, again demonstrating the inverse relationship between activity and defaecation in the open field[2].

Table 1. PHENOTYPIC CORRELATIONS AMONG SINGLE-DAY OPEN-FIELD BEHAVIOURAL SCORES OF MICE FROM TWO INBRED STRAINS AND DERIVED GENERATIONS

Generation	A_1A_2	A_1D_1	A_1D_2	A_2D_1	A_2D_2	D_1D_2	N
P_1 (BALB)	0·34	−0·16	−0·12	−0·06	−0·06	0·45	64
P_2 (C57Bl)	0·20	−0·03	−0·12	−0·01	−0·08	0·17	112
F_1	0·43	−0·37	−0·18	−0·22	−0·42	0·27	415
B_1	0·66	−0·30	−0·18	−0·26	−0·36	0·13	257
B_2	0·39	−0·31	−0·26	−0·13	−0·41	0·24	315
F_2	0·60	−0·28	−0·20	−0·17	−0·44	0·36	637
F_3	0·65	−0·37	−0·31	−0·26	−0·49	0·30	841

A_1, A_2, D_1 and D_2 symbolize activity on days one and two and defaecation on days one and two, respectively.

Heritabilities of single-day activity and defaecation scores and the genetic correlations among them were estimated from parent–offspring comparisons available from data of the F_2 and F_3 generations. These estimates, as well as pooled estimates of r_P from these generations, have been published previously[3], but because the data are useful for estimating r_E and for later comparisons they are presented again in Table 2.

The primary objective of the present communication is to examine the relationship between r_A and r_E. (We are not discussing the possible association between additive genetic values and corresponding environmental deviations, that is, not r_{AE}.) From the data of the present study, r_E can be estimated in two different ways: (1) from the phenotypic correlations of the isogenic generations presented in Table 1; and (2) from substitution of the values from Table 2 into equation (2). Environmental correlations among the single-day open-field behavioural scores were estimated by both methods and are presented in Table 3. (Pooled estimates obtained from the isogenic generations were calculated by weighting the F_1 correlations by two, for the frequency of heterozygotes in the F_2 and F_3 generations is expected to be twice that of either homozygote.) Differences between corresponding estimates of r_E above and below the diagonal could be attributed to sampling error or to the fact that one set (above diagonal) comes from the correlation between environmental deviations only, whereas the other set comes from correlations between environmental plus non-additive genetic deviations. In general, however, corresponding values in Table 3 are in remarkable agreement, especially considering that entirely different methods and generations were involved in their estimation. A comparison of the values in Table 3 with those above the diagonal in Table 2 is also interesting: when the genetic and corresponding environmental correlations are compared, a similar pattern of association is observed.

Table 2. GENETIC CORRELATIONS ± $S.E.$ (ABOVE DIAGONAL), PHENOTYPIC CORRELATIONS (BELOW DIAGONAL) AND HERITABILITIES ± $S.E.$ (MAIN DIAGONAL) OF SINGLE-DAY OPEN-FIELD BEHAVIOURAL SCORES OF MICE IN F_2 AND F_3 GENERATIONS (FROM REF. 3)

	Day 1 activity	Day 2 activity	Day 1 defaecation	Day 2 defaecation
Day 1 activity	(0·28 ± 0·09)	0·94 ± 0·04	−0·51 ± 0·19	−0·89 ± 0·07
Day 2 activity	0·63	(0·09 ± 0·07)	−0·10 ± 0·41	−0·76 ± 0·24
Day 1 defaecation	−0·34	−0·23	(0·14 ± 0·06)	0·20 ± 0·41
Day 2 defaecation	−0·29	−0·47	0·32	(0·07 ± 0·06)

Table 3. ENVIRONMENTAL CORRELATIONS AMONG SINGLE-DAY OPEN-FIELD BEHAVIOURAL SCORES

	Day 1 activity	Day 2 activity	Day 1 defaecation	Day 2 defaecation
Day 1 activity	—	0·35	−0·23	−0·15
Day 2 activity	0·59	—	−0·13	−0·25
Day 1 defaecation	−0·30	−0·13	—	0·29
Day 2 defaecation	−0·21	−0·44	0·34	—

Estimates above diagonal were calculated from pooled phenotypic correlations within isogenic generations, whereas those below diagonal were obtained from solution of equation (2).

Although our data are relatively extensive, the number of possible comparisons between r_A and r_E is not large. Nevertheless, we wish to suggest that r_A and r_E may often be correlated and that such a correlation might, with hindsight, be predicted from evolutionary considerations. Consider, for example, the first pair of characters listed[1] in Falconer's Table 19.1: the genetic correlation between milk yield and butterfat yield is 0·85 and the environmental correlation is 0·96. The magnitude of the genetic correlation indicates that cattle with high additive genetic values for milk yield will also have high additive genetic values for butterfat yield; that is, genic substitutions which result in higher milk production also lead to higher butterfat production. In a similar manner the large environmental correlation indicates that an environment conducive to high milk yield will also promote high butterfat yield. From the standpoint of biological efficiency, it would seem most reasonable that correlated characters should respond similarly to both genetic effects and environmental deviations. Although several of the cases listed by Falconer might serve as counter examples to this argument, the standard errors of estimates of genetic correlations are notoriously large. Nevertheless, individual exceptions may occasionally occur.

Further evidence for the relationship between r_A and r_E is provided by the results of attempts to obtain maximally and minimally heritable factor scores by multivariate analysis of genetic and environmental matrices. Such attempts have been relatively unsuccessful, at least in terms of the degree of separation achieved. Thompson[4,5] has discussed the importance of attempting to isolate factors which maximally represent either genetic or environmental sources of variation. Multivariate analysis of genetic and environmental correlation matrices seems to provide a promising approach which Loehlin and Vandenberg[6] have used in their twin study of human cognitive ability. But factors extracted from two matrices, one representing mostly genetic effects and the other environmental, were basically similar. In a multivariate analysis of matrices of genetic and environmental correlations among morphological and production characters of swine[7], resulting components describing the genetic and environmental correlational patterns were also similar. Thus, in separate studies which used widely different characters and species, multivariate analyses of genetic and environmental correlation matrices achieved little separation. Such lack of separation would be expected if there were an element-by-element association between the two matrices, that is, if r_A and r_E were correlated.

Dislocation of Tones in a Musical Sequence: a Memory Illusion

Computer-generated tonal sequences have several advantages for investigations of immediate memory: the stimulus parameters are simple and can be exactly controlled, and the items cannot be readily rehearsed. Previous studies of memory for pitch have investigated the effect on the differential threshold of blank intervals between the standard and comparison tones[1-3] and of one interpolated tone[4,5].

In the recognition of simple musical sequences the order of the component tones is usually supposed to be well retained; and this assumption is especially important to musical analyses based on information theory[6]. I have, however, found that there can be a rapid loss of such order information in a very simple tonal sequence; namely, the traditional musical scale.

The procedure was as follows. A subject listened to a test tone, which was followed by a sequence of four intervening tones and, after a pause, by a probe tone. The subject was instructed to try to remember the test tone, ignore the four intervening tones if he wished, and then to judge whether the probe tone was or was not of the same pitch as the test tone. All tones lasted for 200 ms. The first five tones were separated by intervals of 300 ms, and there was a 2 s pause before the probe tone (see Fig. 1). The tones were all equally loud and taken from an equal-tempered scale ($A = 435$) ranging just over an octave, from middle C to the C♯ an octave above. When the test and probe tones differed in pitch, the difference was always a semitone (higher in half the instances, and lower in the other half): this is well above the recognition threshold in the absence of intervening tones, even with much longer delays between test and probe[1-3]. The intervening tones were chosen randomly except that no sequence contained repeated tones unless they were specified by the experimental conditions. All the test and probe tone pitches were equally represented in all conditions.

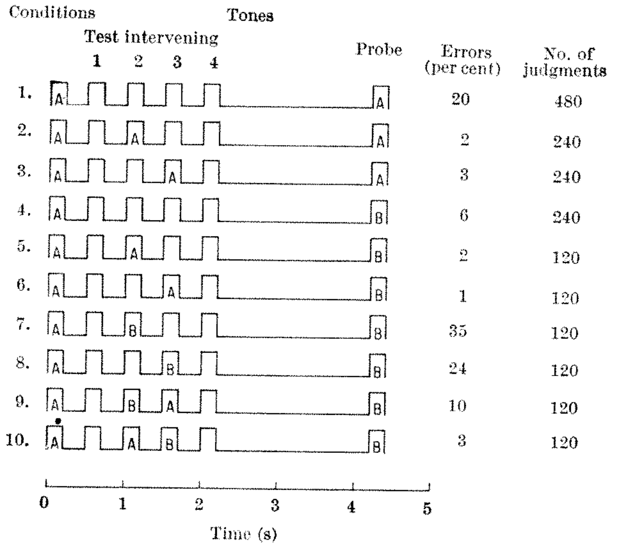

Fig. 1. Arrangement of tonal sequences in the different experimental conditions, with number of judgments and percentage of errors made in each.

Tones were generated by a Wavetek oscillator controlled by a PDP9 computer, and were recorded on tape. Subjects were selected on the basis of obtaining a score of at least 80 per cent correct on a short tape containing similar sequences. The data from the two days of the experiment were averaged.

The experiment investigated the effect on recognition memory of inserting, in the intervening sequence, tones of the same pitch as the test and probe tones. The different experimental conditions are shown in Fig. 1. Here, *A* represents the pitch of the test tone, and of the probe tone when the two are identical. *B* represents the pitch of the probe tone when it differs from *A*. The results (Fig. 1) show that insertion in the intervening sequence of a tone at the same pitch as the probe tone has a striking effect. When the test and probe tones differ in pitch, and neither of these pitches is included in the intervening sequence, errors are only 6 per cent (condition 4). Errors increase to 24 per cent with insertion in the third serial position of the intervening sequence of a tone at the same pitch as the probe tone (condition 8); and to 35 per cent with insertion in the second serial position (condition 7). This effect is significant on a sign test at the 0·01 level. Further, when the test and probe tones are identical in pitch, insertion in the intervening sequence of a tone at that pitch causes a dramatic reduction in errors (2 per cent and 3 per cent in conditions 2 and 3 respectively, compared with 20 per cent in condition 1). This is also significant on a sign test at the 0·01 level.

I propose that subjects showed an increased tendency to err in conditions 7 and 8 because, although they correctly recognized that the probe tone pitch had occurred, they were unable to localize it correctly in the intervening sequence. The same loss of order information could also account for the increased tendency to judge the test and probe tones as the same in conditions 2 and 3 (although the latter finding could result from a trace strengthening effect of repeating the test tone); and this consideration might also be applied to the decreased number of errors when both the test and probe tone pitches are included in the intervening sequence (conditions 9 and 10) rather than the probe tone pitch alone (conditions 7 and 8).

It might be thought that the subjects did not initially hear the sequences correctly; but in a control experiment the identical sequences were played, with the probe tone 2 s before the test tone, and the subjects had no difficulty in making correct judgments.

The conclusion that memory for tonal order deteriorates rapidly, even in the traditional musical scale, can be reconciled with the unquestionable importance of order in tune recognition by assuming that we process tonal information on the basis of higher-order attributes[7] and rapidly discard absolute pitch information.

The preparation of this communication was supported in part by the US Public Health Service and the US National Science Foundation. I thank G. Mandler for support and discussions, and N. H. Anderson, D. Green and D. Rumelhart for comments.

Book Reviews

SAFETY FIRST

Perils of the Peaceful Atom

The Myth of Safe Nuclear Power Plants. By Richard Curtis and Elizabeth Hogan. Pp. xiv + 274. (Gollancz: London, March 1970.) 52*s*.

In the *Perils of the Peaceful Atom*, Richard Curtis extends his range of satire, fiction and non-fiction and, with co-author Elizabeth Hogan, sets out to show that atomic energy presents to man new and horrific dangers, and that government agencies and others in the United States have developed atomic energy unnecessarily, too fast and at too great a cost. Many of the issues raised are particular to the United States, but the general claim of horrific danger, if true, would demand the urgent attention of all nations.

The case unfolds in the following way. First, and the main theme, a pen picture of the unknown and terrible dangers of radioactivity. This is followed by a number of sections describing briefly some accidents, problems of waste storage and transport, a reference to insurance, the heavy demand on cheap uranium supplies, much about the frailty of man and a special disparagement of US administration. The story concludes with the authors' solution to the world power demand of the future, as magnetohydrodynamics, magnetoplasmadynamics, electrogasdynamics, fuel cells, hydroelectric plants, tidal power, geothermal energy and solar energy. "As for clouds, a number of means are being developed for storage of collected solar energy, so that reserves can be built up, literally, for a rainy day."

Because the case rests on many quotations or statements attributed to others, it is important to examine their validity. It is said of the accident at Windscale in 1957 that "authorities had to seize all milk and growing foodstuffs in a four-hundred-square-mile area". In fact, milk was controlled but there was no seizure of any foodstuffs or limitation of its use. This is followed by, "According to Sir John Cockcroft . . . considerably more radioactivity was released at Windscale than is released during an explosion of a Hiroshima-type atom bomb". This statement was not made by Sir John Cockcroft but appeared in 1958 as an erroneous deduction by a science correspondent. The radioactivity released, as compared with the bomb, was less than 1 per cent in terms of iodine and less than 10^{-4} of total gamma activity (measured at one day).

The authors describe the accident to the FERMI reactor in 1966 as an "event as close to Armageddon as this country (USA) has ever known". The International Commission on Radiological Protection has published its evaluation of risks from radiation. Using these and other data, it can be shown that the release of all radioactive material contained in the reactor on that occasion, if carried in the direction of Detroit, a city of 1·5 million, might have led to a risk of about 3×10^{-5} per person that some effect from radiation might appear within twenty years. This is not Armageddon. A similar use of a warlike comparison appears later in the suggestion that a nuclear accident may "wreak death and harm on a level potentially surpassing Hiroshima and Nagasaki". This comparison is not valid. The radiation harm was the result of the direct and intense radiation from the weapon; this does not occur in a reactor accident.

The nuclear industry recognizes the long-term problem involved in the storage of concentrated fission products. There are means for rendering these wastes into insoluble agglomerates of a glass-like material which would make them reasonably secure even against violent upheavals of nature. It may be questioned whether enough effort is invested in solving future problems, but the authors' case is not improved by using language intentionally distorting facts such as, "at present the solutions are stored in tanks whose seams groan under strains metal was never meant to bear".

The authors' treatment of the effluent problems of the industry is confusing. They quote an increase in radioactivity of plankton, fish and ducks as being a thousand to a million times greater. But greater than what ? Also that humans in the Columbia area may have more than 4,000 picocuries of zinc-65; this is only a thousandth part of the permitted body burden and is only one thirtieth of the radioactive potassium carried by all men.

The many inaccuracies and distortions detract from the value of the book. This is a pity because the subject is important and deserves more rigorous selection and checking of the material used. The exaggerated charges made could set back any move towards an open discussion of safety problems. The authors claim that "many AEC pamphlets present over-simplified pictures, almost word cartoons that insult the adult mentality". If so, perhaps these pictures and the attempt to show by over-simplification that the maximum credible accident will cause no harm may be techniques developed, perhaps unwisely, by an industry fearing that any recognition of risk could lead to exaggerated distortions as in the present book.

Although the evidence presented is often erroneous or highly distorted, a rebuttal of the charges made in the book does not imply that there is no need for constant vigilance in determining and applying adequate safety criteria at all stages of an atomic energy programme. A more general form of the authors' argument appears in their foreword: "We are convinced that those who favor our present commercial nuclear power program do not recognize how far we are in actual practice from the high standards and ideal conditions which even the most enthusiastic proponents acknowledge to be essential to public health and safety". Without sharing their conviction expressed in such extreme terms, I accept that no technologically based industry can afford to be complacent about safety. The book may serve a purpose in helping to underline, if rather hysterically, the high standards of engineering, operation and technical assessment required.

COMMUNICATION AND INFORMATION

Information, Mechanism and Meaning

By Donald M. MacKay. Pp. iv + 196. (The MIT Press: Cambridge, Massachusetts, and London, February 1970.) 65*s*.

From time to time, but too seldom, a scientist looks up from his bench or his desk and talks to the educated layman in non-technical terms. Professor MacKay's book records a number of such informal exchanges with the intelligent public. It is a collection of papers, articles and broadcasts, bound together by an introduction and marginal notes, on communication and information. In a book of this kind there is bound to be a certain amount of repetition and even of inconsistency, but this adds verisimilitude to an intellectual autobiography.

To me, the questions raised by the author are often more interesting than his answers. One such question arises from the fact that orthodox information theory, as expounded by Shannon, has no place for the concept of meaning. MacKay devotes quite a lot of space to examining the concept of information, and does some discreet advertising on behalf of his own distinctions between metrical, selective, semantic and structural information content. Unfortunately these distinctions are usually ignored by writers on information theory, but this may be because the idea of information as "negative entropy" lends itself to mathematical development and technical application where the other concepts do not. Perhaps time will redress the balance.

In discussing the nature of meaning the author expresses himself in terms appropriate to automata with well defined "transition probability matrices". Much of what he has to say is clear and cogent, but one may perhaps doubt whether this particular mathematical concept is robust enough to carry such heavy philosophical burdens. Nevertheless, MacKay raises conceptual questions which cannot be ignored, and his book will undoubtedly interest everybody who is seriously concerned with the relation between minds, brains and automata.

CHRISTOPHER LONGUET-HIGGINS

D'ARCY THOMPSON RIDES AGAIN

Symmetry and Function of Biological Systems at the Macromolecular Level

Edited by Arne Engström and Bror Strandberg. (Proceedings of the Eleventh Nobel Symposium held August 26–29, 1968, at Södergarn, Lidingö, in the County of Stockholm.) Pp. 436. (Interscience (Wiley): New York and London; Almqvist and Wiksell: Stockholm, October 1969.) 280*s*.

SYMMETRY, it seems, is in. Possibly it is the delayed impact of the work of the past ten or so years on the structures of complex self-assembly systems, such as viruses and flagella, and the symmetry principles which govern them, that has caused the space groups of late to trip so lightly from biochemists' tongues. Symmetry, it has to be said, is a slender thread to link so diverse a set of articles as are contained in this book, however, and frequently its relevance is lost to view. As with all such volumes, one imagines that the true begetters are the publishers rather than the organizers. Published a year after the event, the papers fall into three categories—those that have in the meantime been published in reputable journals (and a few that are still about to be), the well-worn lecture review (and one or two in this volume present a remarkably threadbare appearance), and the ruminations of the patrician mind, which might otherwise be denied to the hungry scientific proletariat. At best, this last kind can justify the publication of symposium volumes. At worst, and more often, one retains only the impression that all the elaborate and expensive machinery of international congresses and symposia is capable of generating nothing more useful than the occasional blinding cloud of steam. I confess that I addressed myself to the Eleventh Nobel Symposium without enthusiasm. In the event I found much more than one could have hoped that was new, stimulating and even entertaining.

The substance of the book falls into six sections. The first, "Basic Views on Symmetry", is chiefly remarkable for an unaccountable two-page colour plate of the heads of "Australians and Ocean People", but includes also a short, concentrated and stylish exposition by a mathematician (H. S. M. Coxetter) of "The Symmetry Properties of Helices and Concho-spirals". The second section is about "Prediction of the Conformation of Macromolecules", and contains the articles by Scheraga, Ramachandran and Liquori, without which no symposium is nowadays complete. There follows "Interaction between Subunits in Polymeric Proteins", which is an indigestible concoction of X-ray crystallography, electron microscopy and physical chemistry. The paper by Schuster and Ilgenfritz on the kinetics of haemoglobin oxygenation is one of the most substantial and interesting in the book, however, and is a good example of the impact of the Göttingen school on current thinking in molecular biology. "Symmetry and Cooperativity in Biological Membranes" shows the extent to which these have now been sucked into the vortex of allosterism. Nevertheless, however dyspeptic one's response to this prospect, and however much adrenaline, for that matter, one may release on encountering a quotation from Molière at the head (though everyone, of course, to his taste), it must be said that the paper by Changeux is an elegant piece of work. A nicely wrought intellectual structure, balanced on a very pin's tip of experimental fact, it is persuasive to a remarkable degree, and whether or not the concepts turn out in the end to be valid, I do not doubt that it will have its effect on thinking in the field.

The remaining two sections of the book are on "Assembly and Structure of Viruses", which contains particularly an impressive article by Klug, and "Aspects of Macromolecular Assignments in Muscle", with a magisterial chapter by Casper and Cohen, on the nature and significance of polymorphism in protein aggregates, as the centrepiece. There is also a short appendix by Klug called "Point Groups and the Design of Aggregates", which sets out in a dozen pages the principles of symmetry and the manner in which they apply to viruses as the archetypal subunit systems.

There are, then, five or six articles in this volume which are not to be had elsewhere and which encapsulate some of the best achievements in molecular biology of the past few years. There are a good many others which are, I suppose, none the worse for having been published more than once, and only one that struck me as altogether bad and misleading. On this reckoning the book scores a good deal higher than most symposium volumes. It comes at a point in time at which some fundamental ideas incubated over many years by crystallographers, protein chemists and others have come to maturity. The finesse of modern techniques aside, it is D'Arcy Thompson and the great anatomists of the nineteenth century writ small. There are many things here which molecular biologists and their students will wish to ponder on.

W. B. GRATZER

GENETICS BY COMPUTER

Computer Applications by Genetics

Edited by Newton E. Morton. (Proceedings of a Conference sponsored by the University of Hawaii, and the Genetics Study Section, National Institute of General Medical Sciences.) Pp. ix + 167. (University of Hawaii Press: Honolulu, Hawaii, October 1969.) $10.

THIS collection of papers is dedicated to Dr L. H. Snyder and is concerned with the applications of computers in genetics with a strong bias towards human population genetics. The sixteen papers cover a wide variety of topics, and the authors are acknowledged experts in each field. Some of the papers contain a description of the relevant computer programs. The discussion following the reading of some of the papers is included.

There are two papers on Monte Carlo simulation. One, by Levin, discusses the use of simulation in studying the effects of sampling, selection, migration and competition on gene frequencies. Levin discusses in an appendix to his paper some approximate short-cut simulation methods without stressing how much these may reduce the value of the stochastic accuracy that is one of the great advantages of exact simulation. The other paper, by Latter, is an excellent, although perhaps over optimistic, discussion of the use of selection experiments and simulation studies to discriminate between different models of quantitative genetic variation.

There are seven papers on the statistical and computational problems involved in analysing pedigrees, in segregation analysis, and in estimating breeding values, gene frequencies and inbreeding coefficients.

Other more abstract but thorough papers by Morton and Cotterman are concerned with genetic changes in populations isolated by distance and with complex relationships between genotypes and phenotypes. A paper by A. W. F. Edwards gives a rather discouraging review of the state of genetic taxonomy. This will come as no surprise to the more traditionally inclined.

There are interesting papers by Renwick on the use of Bayesian-type methods in studying genetic linkage in man and by W. R. Bodmer and others on the association analysis of a leucocyte system. Renwick emphasizes the need for a study of the non-randomness of genes in linkage maps.

The volume concludes with papers on the simulation of deterministic evolutionary changes in three-locus genetic systems and of equilibrium conditions in certain trimorphic self-incompatible systems.

This book raises certain questions about the place of model-building and simulation studies in biology. An attempt to build a mathematical model of a biological system can often suggest deficiencies in knowledge about that system. This can, and should, lead to further observation or experimentation rather than simulation. There are dangers in attempting to simulate a system when there is too little knowledge about that system. This means that the models that are constructed are, inevitably, too flexible and have far too many unknown parameters in them. These models will, by their very nature, fit the data although they may be low in explanatory or data-summarizing power. My own feeling is that simulation and model-building should only be used when a fair amount is known about the biology of the situation and a model can be constructed that is well founded, fairly specific and contains a small enough number of parameters that they can be satisfactorily estimated by whatever data are available. I do have doubts whether some of the systems studied in this set of papers have reached a stage where model-building and simulation can profitably be applied. Latter's paper contains a useful discussion of some of these points.

This volume will clearly be of interest to all those concerned with genetics and the use of computers in genetics. It will also prove a stimulating experience to those who, although unfamiliar with genetics, are interested in the present state of the subject. There are many interesting questions asked, and by no means have all of them been answered. R. N. CURNOW

INTEGRATED GENETICS

Genetic Organization

Edited by Ernest W. Caspari and Arnold W. Ravin. (A Comprehensive Treatise, Vol. 1.) Pp. xi + 525. (Academic Press: New York and London, December 1969.) 271*s*.

THIS is the first volume of a proposed multi-volume treatise which will deal with the current state of knowledge in genetics. The reason given for producing it (when there are already so many good texts on advances in genetics) is that the discipline seems to be fragmenting, like most biological subjects of any age; so that molecular, developmental and evolutionary geneticists are losing touch with each other's work. Accordingly, the purpose of the treatise is to provide a medium whereby students of genetics can integrate recent advances in all fields into a single coherent structure, and also to reveal gaps in understanding which may indicate profitable fields of research.

In the first section, L. C. Dunn covers the history of genetics in terms of the main streams which have contributed to our present knowledge. The prose is turgid, but cannot conceal the authority of this most experienced genetic historian. Next follows a section by Henry M. Sobell on the structure of the nucleic acids; this is excellently clear and up to date. In section three, J. H. Taylor gives a masterly exposition of a field which he has made very much his own, namely the structure and duplication of chromosomes. In section four, Walter F. Bodmer and Andrew J. Darlington discuss linkage and recombination at the molecular level. This is a lucid account of recent work on microorganisms which sheds light on these topics and on the present state of knowledge on the enzymology of DNA breakage and repair.

In the fifth section, Sterling Emerson writes on linkage and recombination at the chromosome level. This is a very technical account of evidence from a wide range of organisms. This subject is never easy reading, and comprehension is not helped by the complexity of the data which are presented. The review is perhaps written from a more personal viewpoint than others in this volume, and includes a large addendum containing the author's views on the acquisition and handling of certain genetic data. In the sixth and last section, Rhoda F. Grell reviews knowledge of meiotic and somatic pairing. Here, as in the previous section, the density of the genetic jargon makes reading hard work but cannot conceal either the author's deep knowledge of the field or the exhaustiveness with which this knowledge is deployed.

My feeling about this book is that it is essentially a collection of up to date and authoritative reviews at a high intellectual level. While the clarity of exposition varies considerably between the different authors, the thoroughness with which they have performed their task is unquestionable; the relevant literature has been thoroughly dredged (no doubt all the latest techniques of information retrieval have been used). Whether the book will effect its avowed objects is uncertain. Few scientists will have a broad enough background to read it all with understanding (and even fewer will be able to afford to buy it, certainly in Britain). But many will find this volume (and the ensuing ones if the high standard is maintained) invaluable as a reference book, particularly in their own and related fields. It is to be hoped, therefore, that many libraries will be willing to find the money to purchase it. E. H. R. FORD

MEDICAL DIAGNOSIS

Physical Principles of Ultrasonic Diagnosis

By P. N. T. Wells. (Medical Physics Series, Vol. 1.) Pp. viii + 282. (Academic Press: New York and London, November 1969.) $12.50; 80*s*.

IN the course of some ten years ultrasonic diagnosis has advanced from a rather tentative method in the hands of a few pioneers to an accepted technique complementing, but not replacing, the use of X-rays. This progress has involved close collaboration between clinicians, physicists and engineers. The physics is highly specialized but it must be sufficiently understood by all three groups if the potential of the method is to be exploited. A book designed for this purpose is therefore timely and welcome.

It must be said at once that the difficulty of the task has not been shirked by pretending that the subject is simple. To set it out in full detail would require a very large volume, and the author has compromised by summarizing the essentials in a number of well defined sections which are supplemented by a bibliography of more than four hundred selected literature references. Starting from simple wave motion, he deals in succession with the passage of ultrasonic waves through matter, with transducers and with the ultrasonic field. He then discusses the various techniques which are available including the very important ones based on pulse echo and on the Doppler effect. It is at this stage that he introduces a number of typical clinical applications to show the scope as well as the limitations of the methods. Finally, he discusses the possible biological hazard in the use of ultrasonics.

On the whole, these topics are covered adequately and in a balanced manner. A little more information about the physical processes involved in biological damage would have been welcome, but this is a part of the field which is perhaps expanding too rapidly for simple summary. Possible future developments have not been overlooked, for example, the use of ultrasonics in holography of the human body. This book should do much to encourage further development in this important branch of medical diagnosis.

C. B. ALLSOPP

BLADDER CANCERS

Occupational and Environmental Cancers of the Urinary System

By W. C. Hueper. Pp. xix + 465. (Yale University Press: New Haven and London, November 1969.) 180*s*; $20.

DR HUEPER has in effect written two books within the cover of one. The first book is an account of the factors that are known or are suspected to be involved in the development of bladder tumours. The general belief in clinical circles is that bladder tumours are partially, if not completely, produced as the result of chemical constituents in the urine which act on the urinary epithelium and produce neoplasia. This observation, which was first made in 1895 by Rehn, has been confirmed on numerous occasions both experimentally and in human beings. Up until 1937 it was generally believed that the chemical responsible was aniline because many of these tumours occurred in factories where aniline was manufactured, but the work of Hueper in 1937 established that an intermediate product in the production of aniline, β-naphthylamine, was in fact one of the most potent carcinogens available. Not merely was it the first carcinogenic agent that could be identified chemically but it was also a carcinogenic agent producing bladder tumours when applied to experimental animals and to man.

Hueper presents, in this book, a concise and detailed statement about the experimental work of β-naphthylamine and many other similar chemicals which are also carcinogenic. The references are extensive and very comprehensive. There is hardly an experimental paper written on the subject of bladder neoplasia that is not mentioned and discussed in detail.

The aetiological factors, such as smoking, disordered tryptophan metabolites, geographical distribution, social class, and the like, are covered in detail in a critical analysis which evaluates the evidence for each factor and poses many problems to both the clinician and the epidemiologist.

The second book has been written between the lines. It is the story of a man who has spent his life fighting for the recognition that chemicals were dangerous, that industries using these chemicals were producing bladder cancer, and the story relates the frustrations, the difficulties and the woeful obstructions that seem to have been put in his way in order to prevent him establishing the truth of the dangerous nature of these chemicals. This struggle did not occur in one country alone. When Hueper describes the investigation in France carried out by Desoille he states "the reason for the development of bladder tumours became evident when Desoille attempted to investigate . . . as it became apparent that bladder tumours were, in fact, present in the factory. Desoille was asked by the management to leave the premises". In Italy, the manufacturers were among the last of the large-scale producers of β-naphthylamine to abandon making this highly potent carcinogen (1961). The Swiss industry ceased manufacture in 1938, the Germans in 1942, the English in 1952, the Russians in 1950, and most of the factories in the United States in the decade between 1950 and 1960. β-Naphthylamine is still being manufactured in Japan and benzidine is manufactured in Russia and Japan. On p. 80 Hueper states "these data were not obtained without some resistance from the industries concerned. The delay in the publication of the results . . . of the epidemiological investigations . . . which were on hand in 1949, but which were not placed on record until 1954".

This story of the difficulties which have been encountered by research workers in elucidating the true facts about industrial aetiology is one that should be much more widely known among scientists. In Britain, the manufacture of β-naphthylamine stopped in 1949 (not 1952 as stated in the book) and the manufacture of α-naphthylamine and benzidine in 1968–69. It would seem, from reading this book, that Britain has established a leading role in the control of these carcinogenic agents, legislation to prevent manufacture and importation, and compensation for workmen who, as a result of exposure to these chemicals before the recognition of the dangers, have developed bladder cancer.

D. M. WALLACE

CALCIUM PHYSIOLOGY

Mineral Metabolism

An Advanced Treatise. Edited by C. L. Comar and Felix Bronner. Vol. 3: Calcium Physiology. Pp. xvi + 548. (Academic Press: New York and London, October 1969.) 229*s*.

THIS work does not fit easily into any of the categories into which scientific books can usually be classified. It is neither a textbook, a monograph, a work of reference nor the proceedings of a symposium. It is essentially a collection of seven brilliant essays on various aspects of calcium physiology which combine a reasonable survey of previous work with the forceful presentation of a particular thesis. Careful selection of authors and strong editing yield a high degree of internal consistency with a marked emphasis on mathematical treatment.

Marshall's opening chapter on measurements and models of skeletal metabolism sets the tone for the whole work and constitutes a rigorous analysis of bone turnover by a physicist with a strong biological orientation. None the less, it is noticeable that when biological and physical concepts conflict, he shows a marked bias towards the former and almost seems to imply that bone turnover, as understood by bone physiologists, is not a meaningful concept. In fact, he uses technical operations to define biological concepts, instead of the general procedure of defining the concepts first and considering the way in which experimental techniques can measure them. It follows from this approach that some of his terminology, such as augmentation rate, may find little acceptance in the biological field.

Subsequent chapters are perhaps less controversial but equally stimulating. Richelle and Onkelinx review the composition and structure of bone mineral competently and impartially. They lay bare the essence of the controversy as to whether bone mineral is a calcium deficient apatite or a mixture of apatite and octacalcium phosphate, and discuss the available evidence regarding the nature of the carbonate component. They deal with thermodynamic aspects of the relation between bone mineral and tissue fluids and discuss the role of pyrophosphate and other inhibitors, concluding that the concept of a solubility product constant is inadequate to explain the observed data. The authors' known work on the frequency distribution of specific gravity and mineral content of bone powder is restated and discussed in relation to X-ray diffraction patterns and infrared spectra.

Winegrad's review of calcium and striated muscle is a useful, brief survey of intracellular calcium. Walser's chapter on the renal excretion of alkaline earths brings together some useful published data, the discussion of which is rather brief, but which is supported by a bibliography extending to thirty pages. Wasserman's and Taylor's contribution on calcium absorption, on the other hand, is less complete as a review of the subject, but provides an admirable account of their work on the calcium-binding protein.

The concluding chapters are by Manery on calcium and membrane and by Copp on calcium homeostasis. Manery's chapter overlaps to some extent with Winegrad's but may be read as complementary to it. Copp's contribution is inevitably a restatement of his previous views with only minor additions from recent work, but, as would be expected, it is readable and well informed.

The work as a whole is impressive, powerful and somewhat controversial, but it is stimulating and on the whole highly readable. B. E. C. NORDIN

HOST-PARASITE RELATIONS

Immunity to Parasitic Animals

Edited by G. J. Jackson, Robert Herman and Ira Singer. Vol. 1. Pp. ix + 292. (North-Holland: Amsterdam; Appleton-Century-Crofts (Educational): New York, 1969.) 128*s*.

THE first book on the immunology of parasitic infections was that written by Taliaferro more than forty years ago. Since that time there have been notable advances in our knowledge of host-parasite relations, but in spite of all the new information the overall pattern remains obscure and is full of apparent anomalies and unanswered questions. In particular, attempts to control parasitic disease by immunological means have largely proved unrewarding. There are a few vaccines against protozoa and helminths which find application in veterinary practice, but none has proved sufficiently safe and potent to be used in human medicine. There are many reasons for this comparative failure. Not the least is the fascinating intricacy of the life cycles of many of these organisms, providing, at the same time, delight and frustration for those working in this field.

The editors of this review have planned a two volume work, attempting a wide coverage of the subject. The first volume is largely devoted to the immunity (resistance ?) shown by plants and by invertebrate and cold-blooded vertebrate hosts to infection with animal parasites. The various contributors make it plain that these are neglected fields of research. Thus—"Our knowledge of the immune reactions of poikilothermic vertebrates to parasitic protozoa is little more than scant", and "No published reports were found on immunity of amphibians and reptiles to metazoan parasites". What reports there are in these fields tend to be widely dispersed (a paper on agglutinating antibodies in the trout appeared in a journal entitled *The Progressive Fish Culturist*!), and the contributors are to be congratulated on achieving some synthesis of the literature. Their reviews will help to fill awkward gaps in the teaching on host-parasite relations and, it is hoped, will encourage more workers to explore these fields.

Standing apart from the general body of the volume is the review by J. F. A. Sprent on evolutionary aspects of immunity in zooparasitic infections. Sprent attempts to define for the immunologist the special nature of the parasitic association and, for the parasitologist, what is meant by immunity. I doubt whether he succeeds, but the result is a discussion which will greatly interest those already familiar with the two disciplines.

Most workers in the field of parasite immunity are concerned with immunity shown by mammalian and avian hosts. While welcoming this first volume, they will look forward with more interest to the publication of the second. R. J. TERRY

BLOOD PARASITES OF SLOTHS

The Haemoflagellates of Sloths

By J. J. Shaw. (London School of Hygiene and Tropical Medicine, Memoir No. 13.) Pp. xii + 132 + 13 plates. (H. K. Lewis: London, 1969.) 70*s*.

THE sloth is a curious, exotic animal, whose name indicates its habits. It has an equally strange parasite—*Endotrypanum schaudinni*—a trypanosome which inhabits the red blood corpuscles of the animal. This unusual monograph gives an account of the sloth and the parasite. Actually, two genera of sloths are concerned—the two-toed genus *Choloepus* with two species, *C. hoffmanni* and *C. didactylus*, and the three-toed *Bradypus* with two species, *B. griseus* and *B. infuscatus*. Moreover, the researches of the author have demonstrated that two species of *Endotrypanum* (*E. schaudinni* and *E. monterogei*) and two species of trypanosomes (*T. preguici* and *T. leeuwenhoeki*) exist in the blood of these animals. The complex is analysed in relation to the biogeographical background: the habits of the sloths, the type of forest where infection takes place, and the biting arthropods which transmit the haemoflagellates.

The result of this approach is the elucidation, at least in part, of an interesting tropical problem. The author's own work was carried out in the forests of Costa Rica, Panama and Colombia; in addition, past records from Central America, Venezuela, French Guiana and northern Brazil are considered. *Endotrypanum schaudinni* was found in a third of more than a hundred specimens of the two-toed sloth; a new species, *E. monterogei*, was described from two specimens of the sloth; two new trypanosomes were also described from the animal. The Noguchi-Adler test was applied to determine the relationships of these organisms to each other and to a local human strain of *Leishmania* and of *T. cruzi*. They all seem to be immunologically distinct, though *Endotrypanum* is nearer to *Leishmania* than to the three trypanosomes. This affinity is confirmed by the results of cultivation at different temperatures *in vitro*, and by the apparent role of sandflies (*Lutzomyia* spp.) in transmission. The fine structure of *E. schaudinni* is described and the truly intra-erythrocytic position of the organism was confirmed; a peculiar pigment, allied perhaps to malarial haemazoin, was found in the parasites.

The haemoflagellates of sloths have puzzled observers since the discovery of the first in 1908. This monograph is a major contribution to the subject, and although of a specialist nature should prove of interest to the landscape epidemiologist and general biologist.

The book is profusely illustrated by a coloured frontispiece and thirteen line drawings of the organisms, by various photographs of the sloths and their habitats, and by photomicrographs. P. C. C. GARNHAM

READ, LEARN AND INDIGEST

A Textbook of Practical Biology

By George Usher. Pp. 208. (Constable: London, January 1970.) 45*s*.

THIS textbook is a programme of directions for basic practical work designed for A-level candidates particularly where overcrowded classes make it impossible for the student to have adequate individual attention. The author modestly proffers it as a compendium of work he has successfully carried out, the fruits of 12 years' experience in teaching A-level biological sciences.

The arrangement is systematic and covers the essentials of most A-level syllabuses in biology, botany and zoology, together with a great deal of simpler work usually regarded as pre-O-level. Although it is claimed that the student should be able to carry out the work on his own, some of it, notably that on *Drosophila* and on the examination of capillary blood flow and of muscle response in the frog, would need a good deal of supervision and technical support. The sequence is logical. It begins with the physical properties of colloids, the chemistry of cells, enzymes, cell structures and cell division. Then, after some simple experimental work on respiration, the student is taken through a routine dissection of the rat, being first reminded, lest an examination question on it comes as a shock, not to skimp a thorough review of the external features. Gross structure of particular organs of the body is well related to microscopic detail in this section and it is followed by a chapter in which practical work in physiology and histology is correlated. Taxic response, growth and the action of growth hormones are illustrated here using protozoa, arthropods and frog tadpoles. The student is next led through a series of representative types which show the variety of invertebrate and vertebrate animals, then on to the morphology and anatomy of flowering plants and to standard experiments in plant physiology. Variety in the plant kingdom is shown by a further sequence of traditional types. A short section on soil constituents, physical properties and larger soil organisms ends in brief suggestions for simple comparative field work which might be a sound introduction to basic ecological concepts. Meiosis is studied from prepared slides and squashes and there are interesting suggestions for graphing numbers and measurements to illustrate variation. Work on *Drosophila* is cursory and the same might be said of frog and chick embryology.

A useful appendix gives recipes for reagents and media required in the course, and there are lists of apparatus, chemicals and biological materials mentioned in the text.

This is no "open-ended enquiry" approach, although, by following it, students should be helped to see things for themselves and have their expectations confirmed. They are essentially put through a rigorous, systematic routine to fulfil examination requirements and the author makes no bones about it. This course, faithfully followed, supplemented by good text and background reading and backed by adequate field work, would doubtless be crowned by success.

The deliberately simple, occasionally crude, line diagrams are claimed to be of the type and standard expected from a candidate in an examination. Some are eminently satisfactory, but a wealth of excellent examples in recent publications leads us to demand very high quality in this field. Incidentally, I prefer unbroken to dotted lines for joining labels and the parts they indicate. Students are offered very sound advice, especially in observing and recording rat anatomy (page 24), on the desirability for measurement and minimal shading. Directions in the main are very complete and explicit, but there are occasional lapses: "make a 0·5 per cent solution of starch by boiling in water" (page 10). There are some printing errors.

E. J. VINNICOMBE

COLOURFUL GAME BIRDS

A Guide to the Pheasants of the World

By Philip Wayre. Pp. 176. (Hamlyn: London and New York, February 1970. Published for Country Life Books.) 63*s*.

THIS is a thoroughly practical book and carries the authority of an ornithologist and aviculturist who has made a close study of his subject over many years. While not supplanting the larger work by Delacour (who here contributes a foreword) or the earlier monograph by Beebe, it gives an up to date summary of the main facts about each of the forty-eight species constituting the Phasianini tribe of the Phasianidae, and some overall remarks about each of the sixteen genera in which they are placed. There are six introductory chapters of a more general kind, dealing chiefly with avicultural aspects, and three appendices.

The tribe includes not only all the birds that are called pheasants, but also the tragopans, junglefowl and peacocks, with some others that have special names. Apart from the results of introductions by man, they are almost restricted to Asia, chiefly from the western Himalaya eastwards to Japan and Borneo; the natural range of one species extends westwards just into Europe and another species, not discovered until 1936, is exceptional in being an inhabitant of equatorial Africa. The habitats vary from tropical rain forest to mountains 15,000 feet above sea level, and from reed beds to steppes, but most of the species are forest dwellers.

The birds are of substantial size and good to eat; the males are in most instances highly colourful; and the specific ranges are often very restricted. These facts have helped to bring at least sixteen of the species within danger of extinction at the present time. Fortunately, they mostly thrive in captivity and many of them readily breed. The Pheasant Trust, of which Philip Wayre is honorary director, has been notably successful in building up captive stocks; and in 1937 it was able to return thirty Swinhoe's pheasants to Formosa, where the species is endemic and was on the verge of extinction in the wild state. Such efforts, of course, need to be reinforced by local measures to conserve suitable habitats and to protect the birds.

There are good colour illustrations of the males of forty-six species by J. C. Harrison. No females are figured, but their plumages, generally cryptic, are described in the text. The volume is well produced.

LANDSBOROUGH THOMSON

CRYSTALS AND ROCKS

Introduction to Mineralogy

Crystallography and Petrology. By Carl W. Correns. Second edition, in cooperation with Josef Zemann (Part 1) and Sigmund Koritnig (Mineral Tables). Translated by William D. Johns. Pp. xi + 484. (Allen and Unwin: London; Springer–Verlag: Berlin, January 1970.) 105*s*.

IT is exceptional nowadays for a single textbook to provide adequate treatment, even at an elementary level, of all the diverse fields of knowledge required by the modern mineralogy student. But this Professor Correns achieved with considerable success in the first edition of his book which appeared in 1949. The subjects covered were crystallography, crystal chemistry, optics, petrology, weathering and soil formation, ore deposits and geochemistry. Then, as now, the extensive mineralogical tables were compiled by Professor Koritnig and mineralogy was approached through petrology. In the second edition an extensive revision of part one, "Crystallography", has been undertaken by Professor Zemann; that of part two, "Petrology", has remained with Professor Correns. The new volume is about a fifth larger than its predecessor, but extensive deletions of older matter have permitted substantial amounts of new material to be added. Additional topics include volatiles, metamorphic facies, and isotope geochemistry. The layout of the tables has been improved and they now include a considerable amount of new information not mentioned in the text.

Part one is divided into four sections, crystal symmetry (misnamed mathematics); crystal chemistry; crystal physics (chiefly optics and X-ray crystallography); and crystal growth and dissolution. Symmetry is treated formally by way of morphology, but later, ideas of lattice symmetry are developed which serve to introduce space groups. The crystal chemistry is just what is required, but the X-ray section would have been strengthened by a fuller treatment of intensities, accurate determination of cell dimensions, choice of radiation, and some mention of diffractometers. In a section on crystal physics, surely an attempt should be made to justify the indicatrix. Part two begins with an interesting account of crystallization processes and phase diagrams up to ternaries; it then leads on to hydrous systems. The sections on igneous and metamorphic petrology are much too condensed, but the account on the role of volatiles is quite the best to appear in an elementary text. There are further chapters on sedimentary rocks, metasomatism, the development of tectonites, and geochemistry.

The account seems to have lost little in translation, the diagrams are excellent and the paper, although still of two types, is of good quality. A bibliography is provided as well as author and subject indexes. The work throughout is written with authority and reaches a high standard, but one is left with the feeling that this vast field would have been covered much better by two books.

I. D. Muir

OPTICS FOR UNDERGRADUATES

University Optics

Vol. 1. By D. W. Tenquist, R. M. Whittle and J. Yarwood. Pp. viii + 349. (Iliffe: London, October 1969.) 70*s*.

In the preface the authors describe this text as "intended to cover the requirements in the subject of optics for the student preparing for Part 1 of an honours degree in physics, a general degree in science or ancillary physics to an honours degree in chemistry or other main discipline". Of the material covered in volume one, the first three chapters deal with geometrical optics and optical instruments. These chapters deal with these difficult subjects clearly and concisely. Refractometry and photometry take up nearly one-third of the volume and it is this extensive treatment of practical optics which distinguishes this book from the many other available texts. The velocity of light is given a chapter to itself, which seems a little excessive. The wave theory of light is followed by sections on interference, diffraction and resolving power.

There are worked examples throughout the text and questions from various university degree examinations are included at the end of each chapter, with answers to the numerical problems at the end of the book. The treatment throughout is traditional, in contrast with other recent undergraduate books in optics. While there is nothing particularly novel in either presentation or material, the writing is thorough and accurate. Special attention is paid to practical details, particularly in those sections dealing with optical measurements and instruments. There are plenty of clear, well-drawn diagrams which supplement the text, but it is a pity that the publisher did not choose a better quality of paper.

To sum up, this is a useful book which, while suitable for applied physics and ancillary physics courses, probably does not present sufficient challenge for a first year undergraduate intending to specialize in physics.

D. J. Bradley

Obituaries

Mrs M. J. Richards

Mrs M. J. Richards (Dr Maud Norris) will be remembered chiefly for her work as a locust entomologist, in which she had a world-wide reputation. It was Mrs Richards who discovered the maturation pheromone of the desert locust in 1954. Her association with locusts and the Anti-Locust Research Centre came about almost by accident and in spite of the fact that her early work had been on pests of stored products. When the Anti-Locust Research Centre became an independent research institute in 1945, the director at that time, Dr B. P. (now Sir Boris) Uvarov, was looking for a scientist to run the laboratory. Mrs Richards expressed interest, was given a research grant in 1946 and from then until December 1969 never gave up locust work.

Maud Richards was born in Plymouth in 1907, the daughter of a naval officer, and was educated at several schools including Cheltenham Ladies' College. At King's College, London, she obtained first class honours in zoology in 1928. She became a demonstrator at King's College and then held a DSIR grant in the Department of Zoology and Applied Entomology of Imperial College, where she obtained her PhD degree. It was also here that she met her husband, Professor O. W. Richards, who was then a lecturer in the department, and she was married in 1931. From 1932–34 she was a research assistant at Imperial College and took up what was to remain the major theme of all her work, the reproductive processes and associated behaviour of insects. Her three papers on the stored products moth *Ephestia*, published in 1932, 1933 and 1934 and still quoted today, typify her broad approach and include studies of the structure and functions of the reproductive organs, the effect of food and external factors, and physiology.

After 1934, when she stopped working full time, she did part time work in the British Museum (Natural History) on the *Zoological Record* as well as voluntary work at the Pest Infestation Laboratory in Slough. In 1937 she accompanied her husband to British Guiana, sharing his Leverhulme grant, to collaborate on the biology of social wasps; a notable joint paper resulted later. In 1946 Mrs Richards joined the ALRC as a research fellow, was then appointed an SSO and finally promoted to PSO, which she remained until her death this year. While there she published more than twenty-five important papers on locust biology and physiology, and built up an international reputation for her work on the effects of grouping and phases in locust biology. She made important observations on the effects of density, food and photoperiod on locust reproduction and maturation, but clearly something else more elusive was involved and in 1954 her patience and persistence were rewarded with the discovery of a chemical influence, the maturation pheromone. This was a finding of great importance and was one of the first demonstrations that this type of compound existed.

Mrs Richards's research stimulated further work in the ALRC and in many other laboratories in this field, resulting directly in the discovery of more pheromones. She herself found others connected with reproduction and, recently, a chemical functioning in gregarious oviposition behaviour of locusts. Indirectly her work generated interest in chemicals biologically active in locust reproduction, particularly plant chemicals that trigger maturation.

She was now well known internationally, and was awarded the DSc of the University of London in 1964. She was much in demand for international symposia, treating this recognition with characteristic modesty; she was also interested in field work overseas, enjoying these visits not only for the experience itself but because they provided her with insights for further laboratory work. During the 1960s she went abroad frequently. In probably the most interesting and arduous of her trips she and Professor Richards joined the Royal Society and Royal Geographical Society Expedition to the Mato Grosso in Brazil in 1968. She passed off the hardships of the life there with characteristic calmness and said that she was much more interested in the great variety of grasshoppers that she found in the forest than in the difficulties of camp life.

Mrs Richards was one of the longest-serving members of the Anti-Locust Research Centre; she had a quiet, friendly, unassuming manner and never sought the limelight. But she could be roused when scientists, be they colleagues or not, drew unwarranted conclusions from insufficient data, and then she gently but firmly drew attention to the lapse. Her help and counsel were much in demand by her colleagues at home and overseas, and she was always ready to assist them. She will be sadly missed not only in the centre but by locust scientists all over the world.

Correspondence

A-levels and University Performance

SIR,—I would like to comment on D. G. Bagg's interesting article on A-levels and university performance (*Nature*, **225**, 1105; 1970), and to take a different view of the predictive value of examinations based upon a less literal interpretation of the results of analysis and consequently reaching more conventional conclusions.

I have made an investigation of the predictive validity of examinations from university entry qualifications to final degree for all candidates for the honours degree in mechanical engineering of the University of Salford from 1959 to 1964. This study is continuing; there is, however, a time delay of five years to allow for students who require five years to complete the normal four-year course. As in Bagg's work, the study is longitudinal, but attempts to predict only from one sessional examination to the following sessional or final examination taken one year later. The predictive criterion used is the average mark per script obtained by each candidate in each of the successive examinations. This criterion was selected because it gave significantly better correlation from year to year than the mark in any individual subject and also because the frequency distribution of average mark per script was found to be very close to a normal distribution for sessional and final examinations, thus satisfying an important condition for a linear regression model.

Table 1

Entry qualification	No. of candidates	Average mark per script	Correlation coefficient
GCE Advanced level in three or more subjects, including maths and physics	243	56·7	0·286
GCE Advanced level in maths and physics only	187	53·1	0·292
Ordinary National Diploma	40	58·0	0·461
Ordinary National Certificate (internally examined)	155	55·3	0·285
Ordinary National Certificate (externally examined, with four subjects)	121	54·8	0·422
Ordinary National Certificate (externally examined, with three subjects)	65	53·1	0·213

The condition of normal frequency distribution was not satisfied by the marks obtained in the entry qualifying examinations, these marks tending to be biased towards the minimum acceptable standards for the course. For this reason and because of the variety of entry qualifications offered by students, which in turn led to relatively few students in some of the categories of entry group, linear regression equations were not calculated to predict first-year sessional examination performance from entry qualification performance. However, product-moment correlation coefficients between entry qualification performance (divided into six categories of qualification) and average mark per script obtained in the first-year sessional examination were calculated and provide an indication of the degree of relationship between these variables. The average mark per script obtained in the first-year sessional examinations for all candidates in each of the six entry qualification categories was also calculated and is shown, with the correlation coefficients, in Table 1.

The regression equations and correlation coefficients for performance in sessional and final examinations of candidates in successive years of the course are shown in Table 2, in which $x_{1,2,3,4}$ denotes the average mark per script obtained by a candidate in the first, second and third year sessional examinations and the final examinations respectively.

Table 2

Sessional examination	No. of candidates	Correlation coefficient	Predicted mark
First to second	265	0·660	$x_2 = 11{\cdot}82 + 0{\cdot}745\ x_1$
Second to third	232	0·723	$x_3 = 6{\cdot}58 + 0{\cdot}916\ x_2$
Third to final	233	0·736	$x_4 = 4{\cdot}63 + 0{\cdot}887\ x_3$

The correlation coefficients shown in Tables 1 and 2 indicate that performances in successive university examinations are more closely related than performance in GCE Advanced level or other entry qualifying examinations with subsequent performance in university examinations. It would be surprising if this were not so, in view of the relative homogeneity of the university situation compared with the variety of examining boards, schools and social backgrounds of the candidates before university entrance.

This factor, in conjunction with the reasonable surmise that undergraduates are, by the time they begin university courses, already highly selected from the general population as far as examination performance is concerned, leads me to conclude that final degree performance cannot be expected to bear marked relationship to performance in A-level examinations as a whole. This relationship can be expected to weaken with performance in a single A-level subject and to become negligible if factors affecting performance which are common to two or more subjects are removed in the regression analysis. This effect is clear in the multiple regression equations presented in Bagg's analysis. This is not to argue that A-level grades are unreliable and possibly hazardous predictors of future academic performance but that to expect more than a general indication of academic ability is to expect too much. That A-level performance does provide such an indication has been demonstrated by Petch[1], who states that of a sample of 3,523 students who entered a university in October 1956, after being examined by the Joint Matriculation Board, nine out of ten justified their selection by subsequently completing degree courses and that incidence of premature termination of courses was higher for less well qualified groups of students than for groups which obtained better results at Advanced level. An additional inference which may be drawn from Table 1 is that A-level performance is not the only indicator of the potential ability of undergraduates, and I suspect that this conclusion is as valid for other disciplines as it is for engineering.

Yours faithfully,

R. R. PLATT

Department of Mechanical Engineering,
University of Salford.

---

University News

Geoffrey V. Ball, head of the Department of Ophthalmic Optics, has been appointed professor of ophthalmic optics in the **University of Aston in Birmingham**, and **Dr Michael R. W. Brown**, Bath University of Technology, has been appointed professor and head of the Department of Pharmacy, also in the **University of Aston in Birmingham.**

ERRATUM. In the review of "A Short History of Botany in the United States" (*Nature*, **225**, 1078; 1970), the second and third sentences of the first paragraph should read: "The eleventh International Botanical Congress was held in Seattle in August 1968. This volume outlines the growth of knowledge . . ."

ERRATUM. In the article "Bremsstrahlung Radiation in an Intense Magnetic Field and Emission from Pulsars" by Hong-Yee Chiu and Vittorio Canuto (*Nature*, **225**, 1230; 1970), equation 5 should read:

$$\alpha_\omega = \frac{8\pi^3 c^2}{n_r{}^2\omega^2}\, 2m \int_0^\infty \left[f(p_z{}')\, \frac{\partial}{\partial p_z{}'} \left(\frac{Q_\omega(p_z{}')}{p_z{}' + p_z}\right) + f(-p_z{}')\, \frac{\partial}{\partial p_z{}'} \left(\frac{Q_\omega(p_z{}')}{p_z{}' - p_z}\right)\right] \mathrm{d}p_z{}' \qquad (5)$$

ERRATUM. In the article "The Man who Lived with Australopithecines" (*Nature*, **225**, 1188; 1970), it was implied that the stone industry recovered from the Swartkrans cave site was contemporaneous with the Oldowan culture from Bed I at Olduvai, thus making it about 1·75 million years old. The comparison should, however, have been with the much younger culture from Bed II at Olduvai.

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Exchange: Furnished 3 or 4-bedroomed house/apartment near the University of California, San Francisco, required for one year from July 1, 1970. Would exchange for a furnished 4-bedroomed house with central heating in Highgate, London N6, very near Highgate tube station. Please contact Dr M. de Swiet, Medical Unit, University College Hospital Medical School, University Street, London WC1 (telephone 01-387 5861).

Vacant: From July 1 to September 30, 1970. Furnished house, 3 bedrooms, central heating, 5 miles from St Andrews and the University. Please contact Dr David Scott, Department of Zoology, The University, St Andrews, Fife, Scotland.

Wanted: From early June to either end of July or preferably end of September, a 3-bedroomed house for botanist, wife and two children returning to Cambridge for study leave. Within three-mile radius of city centre preferred. Please contact W. Hadfield, Tea Research Association, Jorhat-8, Assam, India.

Wanted: Furnished flat or house in London with easy access to Imperial College, from beginning of June 1970 to end of January 1971, for American professor and family. Possibility exchange accommodation London/Harvard. Please contact Mrs B. Davidson, C.C.A., Imperial College, London SW7 (telephone 01-589 5111, ext. 1408).

Wanted: Small house or flat for married couple in the vicinity of the MRC Clinical Research Centre at Northwick Park, Harrow, Middlesex, for any period of time exceeding 3 months from September 15, 1970. Please contact Dr Philip Davies, Department of Medicine, New York University School of Medicine, 550 First Avenue, New York, NY 10016, USA.

British Diary

Monday, April 20

Education (6 p.m.) Sir James Tait, Royal Society of Arts, at John Adam Street, Adelphi, London WC2. (First of three Cantor Lectures on Training for Industry.)

Large Scale Integration in Microelectronics (7.30 p.m.) Mr D. D. Jones, Institution of Electronic and Radio Engineers, at the BBC Engineering Training Centre, Woodnorton, Evesham.

PAM Graded Concentric Windings for 2-speed Single-phase Induction Motors (5.30 p.m.) Dr A. R. W. Broadway and Mr M. R. Weatherley, Institution of Electrical Engineers, at Savoy Place, London WC2.

Perfumery (three-day symposium) British Society of Perfumers; and the Society of Cosmetic Chemists of Great Britain, at the Grand Hotel, Eastbourne, Sussex.

Recent Developments in Extrusion (6.45 p.m.) Mr D. Grant, Plastics Institute, at the Waldorf Hotel, Cooper Street, Manchester.

Skynet (10 a.m. colloquium) Institution of Electronic and Radio Engineers, Joint IEE/IERE Communications Group, at the Institution of Electrical Engineers, Savoy Place, London WC2.

Tuesday, April 21

Automation of Gas Chromatography (8 p.m.) Dr D. R. Deans, Society for Analytical Chemistry; and the Royal Institute of Chemistry, at Constantine College of Technology, Borough Road, Middlesbrough.

Cresol—Its Production and Use (6.30 p.m.) Dr D. McNeil, Society of Chemical Industry, at the University, Southampton.

Lasers and Their Applications (7.15 p.m.) Institution of Electrical Engineers, at Harwood House College, Bletchley, Bucks.

Organic Photochemistry (two-day symposium) University of Manchester Institute of Science and Technology, Sackville Street, Manchester 1.

Pyro-electric Materials for Infra-red Detectors (5.30 p.m.) Dr E. H. Putley, Institution of Electrical Engineers, at Savoy Place, London WC2.

Solar Studies with special reference to Space Observations (two-day discussion meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

Visual Topology (5.30 p.m.) Mr Edward Ironmonger, Royal Institution at 21 Albemarle Street, London W1. (Lecture for Sixth Form Pupils from Schools in London and the Home Counties. To be repeated on April 22, 28 and 29.)

Why Hybrid Computers? (10 a.m. colloquium) Institution of Electrical Engineers, at Savoy Place, London WC2.

Wednesday, April 22

Annual Meeting (6 p.m.) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Automatic Analysis—an Industrial Viewpoint (6.45 p.m.) Mr P. G. Jeffery, Society for Analytical Chemistry; and the Royal Institute of Chemistry, at Luton College of Technology, Luton.

Logic as the Science of Mathematical Reasoning (5.30 p.m.) Professor Abraham Robinson (Yale University), University College London, in the Engineering Theatre, Malet Place, London WC1. (Further lectures on April 27 and May 1.)

Schools Project Technology (7.30 p.m.) Institution of Electronic and Radio Engineers, in the Department of Electrical Engineering, The University, Liverpool.

Real-Time Computer Model (Business Games) Mr D. Simpson, Institution of Electronic and Radio Engineers, at 9 Bedford Square, London WC1.

Science and the Rule of Thumb Approach (7.30 p.m.) Mr G. H. Hutchinson, Oil and Colour Chemists' Association, at the Carlton Hotel, North Bridge, Edinburgh.

Telecommunications Support for the Apollo Program (5.30 p.m.) Mr Lorne M. Robinson, Institution of Electrical Engineers, at Savoy Place, London WC2.

Thursday, April 23

Automatic Trains on the Victoria Line (7 p.m.) Mr R. I. M. Arthurton, Institution of Electronic and Radio Engineers, at Medway College of Technology, Chatham, Kent.

Carbon Fibres (7.30 p.m.) Mr N. Judd, Plastics Institute, at the Old Nags Head, Jackson Row, Lloyd Street, Manchester, 2.

CIMAC—Survey of Noise (6 p.m. discussion) Institution of Mechanical Engineers, Combustion Engines Group, at 1 Birdcage Walk, London SW1.

Comparison of Chromatographic Techniques (2.30 p.m.) Society for Analytical Chemistry, Chromatography and Electrophoresis Group, at the Portsmouth Polytechnic, Burnaby Road, Portsmouth.

Quasars and Radiogalaxies (5.30 p.m.) Professor F. Hoyle, FRS, Institution of Electrical Engineers, at Savoy Place, London WC2 (61st Kelvin Lecture.)

The Photoelectron Spectra of Some Molecules Containing the C≡N Group, Mr R. F. Lake and Sir Harold Thompson, CBE, FRS, and

Vibrational Relaxation in Pure CO_2 and CO_2 Mixtures, Mr C. J. S. M. Simpson and Mr T. R. D. Chandler (4.30 p.m.) Royal Society, at 6 Carlton House Terrace, London SW1.

Friday, April 24

Complexolytic Photoreactivity and Low-Energy Photosensitization (1 p.m.) Professor G. O. Schenck, Royal Institution, at 21 Albemarle Street, London W1.

Experimental Techniques for the Detection of Ion Movement in Solids, Society for Electrochemistry, Solid State Sub-Group, at the Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Low-light Vision (2.30 p.m. colloquium) Institution of Electrical Engineers, at Savoy Place, London WC2.

Models and Molecules (9 p.m.) Professor W. D. Ollis, Royal Institution, at 21 Albemarle Street, London W1.

Non-standard Analysis. I. Analytic Theory of Polynomicals (5.30 p.m.) Professor Abraham Robinson (Yale University), University College London, in the Engineering Theatre, Malet Place, London WC1.

Spring Scientific Meeting (11.30 a.m.) Fisheries Society of the British Isles, in the Large Meeting Room of the Zoological Society, Regent's Park, London NW1.

Monday, April 27

Apprenticeship and Industrial Training (6 p.m.) Mr Cyril R. English, Royal Society of Arts, at John Adam Street, London WC2. (Second of three Cantor Lectures on Training for Industry.)

Contact Problems in Machines using Thyristor Assisted Communication (5.30 p.m.) Professor J. J. Bates, Mr S. Stanway and Mr R. F. Sansum, Institution of Electrical Engineers, at Savoy Place, London WC2.

Escalators and Travolators (6 p.m.) Mr C. W. Hardie, Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Gunn Domain Logic (5.30 p.m.) Dr H. L. Hartnagel, Institution of Electrical Engineers, at Savoy Place, London WC2.

Quasi-stellar Objects (5.30 p.m.) Professor G. Burbidge (University of California), University College London, in the Physics Theatre, Gower Street, London WC1.

The Evolution of a Microbial Metabolic Pathway (5.30 p.m.) Professor Roger Y. Stanier (University of California), University College London, in the Botany Theatre, Gower Street, London WC1.

UNIVERSITY OF QUEENSLAND
AUSTRALIA
CHAIR IN CIVIL ENGINEERING

Applications are invited for appointment to a Chair in Civil Engineering. This position has become vacant following the death of Professor J. H. Lavery. There are two Chairs of Civil Engineering in the University, and Professor G. R. McKay is Head of the Department.

The Professor's special interest should be in Structures, and he will be responsible for all departmental activities in this area, including undergraduate and postgraduate teaching and research. He will also be required to participate in the administration of the Department as a whole. In addition, he will be expected to maintain an effective liaison with the local profession, and to assist in the administration and development of existing testing and professional advisory services. He may be required to advise the University on building matters.

He should have broad professional experience within the specified area, and this should include competence in design, analysis, construction and testing procedures.

The salary for a Professor is $A12,000 per annum. (Salary scales are at present under review.)

The University provides superannuation similar to F.S.S.U., housing assistance, study leave and travel grants for a permanent appointee of Lecturer status and above.

Additional information and application forms will be supplied upon request to the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London, WC1H OPF.

Applications close in London and Brisbane on May 22, 1970. (1600)

SOUTH WORCESTERSHIRE HOSPITAL MANAGEMENT COMMITTEE
SENIOR TECHNICIAN II

required for new expanding biochemistry department at Worcester Royal Infirmary (Ronkswood Branch). Modern apparatus including isotope equipment available. Technician taking F.I.M.L.T. or Special examination in biochemistry might be considered with prospect of promotion to Senior Grade II on gaining qualification.

Applications stating age, qualifications and experience, naming two referees to Hospital Secretary, Worcester Royal Infirmary (Castle Street Branch) Worcester. (1578)

BIRKBECK COLLEGE
(UNIVERSITY OF LONDON)

Applications are invited for the post of LECTURER IN ZOOLOGY. Candidates who have training and research interests in physiology will be preferred. Salary scale: £1,240 by £115 to £2,045 by £115 to £2,850 per annum, plus London allowance of £60 per annum; the initial salary will not exceed £1,470 per annum.

Further particulars may be obtained from the Secretary, Birkbeck College, Malet Street, W.C.1. Closing date: May 4, 1970. (1547)

APPLICATIONS ARE INVITED FOR ADmission to graduate programmes leading to Ph.D. or M.Sc. degrees. Teaching assistantships and fellowships are available to students with B.Sc. degrees and to persons with professional degrees. Research emphasis is on the biochemistry of calcified tissues, with particular emphasis on the protein matrix of these tissues.—For further information write to the Chairman, Committee on the Graduate Studies, Faculty of Dentistry, The University of Alberta, Edmonton 7, Alberta, Canada. (1549)

CSIRO

RESEARCH ENGINEER /SCIENTIST (AERODYNAMIC INVESTIGATIONS)

AUSTRALIA

DIVISION OF MECHANICAL ENGINEERING

GENERAL The Division of Mechanical Engineering of the Commonwealth Scientific and Industrial Research Organization, located at Highett, Victoria, has extended its activities to include aerodynamic research, with an emphasis on fan and duct flows. Experimental facilities, including air moving equipment and instrumentation, have recently been commissioned and are currently being used for research on axial flow fans, short high efficiency diffusers, aerodynamic noise, and a variety of airflow problems associated with mine ventilation, cooling towers, air conditioning, etc. As part of the expansion programme, initial steps have been taken in the design of a moderately large return-circuit wind tunnel.

DUTIES The appointee will be required to participate in the current diffuser research programme which has as its main aim the development of high efficiency short diffusers. The investigations include basic experimental studies and specific tasks undertaken for industry in respect to application aspects.

QUALIFICATIONS Applicants should have a Ph.D. degree or postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability. Previous experience in boundary layer studies is desirable but not essential.

SALARY Depending upon qualifications and experience, the appointment will be made within the salary range of Research Scientist, $A6,139–$A7,789 p.a., or Senior Research Scientist, $A8,105–$A9,448 p.a. Salary rates for women are $A428 p.a. less than the corresponding rates for men. Promotion within CSIRO to a higher classification is determined by merit.

CONDITIONS The appointment will be initially for a fixed term of three years, after which, if mutually desired, either an extension of tenure or appointment for an indefinite period will be considered. The appointment will be conditional upon passing a medical examination and an initial probationary period of twelve months may be specified. An indefinite appointment carries with it Commonwealth Superannuation Fund or Provident Account privileges. Further details supplied on application.

Applications, (quoting Appointment No: 430/283), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach:

Mr. R. F. Turnbull,
Chief Scientific Liaison Officer,
Australian Scientific Liaison Office,
64-78 Kingsway, LONDON, WC2B 6BD by the *22nd May, 1970.*

Applications in U.S.A. and Canada should be sent to The Scientific Attaché, Australian Embassy, 1601 Massachusetts Ave. NW, WASHINGTON DC 20036.

(1553)

WESTFIELD COLLEGE
(UNIVERSITY OF LONDON)

DEPARTMENT OF ZOOLOGY

Applications are invited from men and women graduates for the post of LECTURER IN ZOOLOGY from October 1, 1970.

Further particulars should be obtained from the Deputy College Secretary, Westfield College, Kidderpore Avenue, Hampstead, N.W.3, to whom applications (six copies), stating date of birth, qualifications and experience, together with the names of two referees, should be submitted by May 22, 1970. (1522)

IMPERIAL COLLEGE

Applications are invited from qualified chemists, physicists, chemical engineers or mineral technologists for the position of research assistant to work on the practical development of a new flocculation process. The project is sponsored by English China Clays Ltd. It will require a critical analysis of the theory of flocculation and the design and evaluation of new plant and offers an unusual challenge for an inventive scientist. Salary £1,500 to £2,000 per annum plus F.S.S.U.

Applications to Professor M. G. Fleming, Department of Mineral Technology, South Kensington, London, S.W.7, within one month of the date of this advertisement.

Research opportunities in the Netherlands with Philips

PHILIPS

The PHILIPS RESEARCH Laboratories,
near Eindhoven are looking for

ph.d's

mathematicians, mathematical physicists, applied mathematicians, mathematical engineers and numerical analysts, to work on mathematical problems arising in physics, chemistry, mechanical engineering, electrical engineering, thermodynamics, hydrodynamics, combinatorial and logic design.

The men we seek will collaborate with colleagues and with experimental teams involved in problems that require model formulation, analysis, numerical methods and computer software development.

Traditionally, a wide measure of freedom is enjoyed by research workers in our laboratory.

We believe that this engenders a fundamental approach to problems.
Members of the laboratory are encouraged to publish the results of their investigations and to contribute to international conferences.

Application letters, with curriculum vitae, references and titles of publications are requested to be sent to
N.V. Philips' Gloeilampenfabrieken
Personnel Department, Ir. H. P. Maas Geesteranus
Eindhoven, the Netherlands.

N.V. Philips' Gloeilampenfabrieken,
Personnel Department, Eindhoven, the Netherlands.

PHILIPS

(1507)

UNIVERSITY OF WALES

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for the following posts:

LECTURER/RESEARCH DEMONSTRATOR IN MICROBIOLOGY

DEPARTMENT OF BOTANY

The posts will be tenable for one year from October 1, 1970, with the possibility of renewal. Candidates in any field of Microbiology will be considered, but those with interests in Virology or Marine Microbiology may receive preference.

The salary will be within the range £1,240 to £1,585 for the Lectureship, and £1,010 to £1,065 for the Research Demonstratorship, according to age, qualifications and experience. Both posts carry F.S.S.U. benefits.

Closing date Thursday, April 30, 1970.

LECTURER IN CHEMICAL ENGINEERING

DEPARTMENT OF CHEMICAL ENGINEERING

The appointment will be tenable from October 1, 1970. The salary will be on the scale £1,240 to £2,850 per annum, plus F.S.S.U. benefits.

The Head of the Department, Professor J. F. Richardson, would welcome informal enquiries from potential applicants.

Closing date Saturday, April 25, 1970.

Further particulars, quoting Ref. No. B6, may be obtained from the Registrar, University College of Swansea, Singleton Park, Swansea, Glam, SA2 8PP, to whom applications should be sent by the above specified dates. (1458)

UNIVERSITY OF MANCHESTER

LECTURER IN PHYSIOLOGY

Applications are invited for this post from candidates with a good honours degree in Physiology or related subjects, or with medical qualifications registrable in this country. Appointment will be made in the range £1,240 to £1,585 per annum. F.S.S.U. where appropriate.

Particulars and application forms (returnable by May 2) from the Registrar, The University, Manchester, M13 9PL. Quote ref : 69/70/Na. (1476)

DEPARTMENT OF PHYSICS

UNIVERSITY OF MANITOBA

Offers generous assistance to highly qualified students wishing to do graduate work in physics. Extensive and modern facilities for work in nuclear structure and reactions, solid state, low temperature, atomic physics, and cosmic rays are available.

For information apply to: Head, Department of Physics, University of Manitoba, Winnipeg 19, Man. (X1310)

HAILE SELASSIE I AIR FORCE ACADEMY

Applications are invited for a post of Assistant Professorship in the Mathematics Department. Applicants will be required to teach Mathematics in the First, Second and Third Year.

QUALIFICATIONS: Holders of M.S. in Mathematics with a minimum of three years' teaching experience.

Post to be assumed September, 1970.

SALARY: Eth.$15,000 net per annum (Eth.$6 equals £1 sterling). Family passages and accommodation provided. Three-year contract, renewable if agreed upon by the two parties.

Applications and inquiries to: The Dean of Science Faculty, Haile Selassie I University, P.O. Box 1176, Addis Ababa, ETHIOPIA. (1325)

CSIRO

RESEARCH APPOINTMENT IN BIOLOGICAL CONTROL

AUSTRALIA

DIVISION OF ENTOMOLOGY

GENERAL Applications are invited for appointment as Research Scientist (Biological Control) with the Division of Entomology of the Commonwealth Scientific and Industrial Research Organization, located at Canberra, A.C.T. The Division of Entomology is the main centre in Australia for basic research on insects and is also actively engaged on many problems of economic importance; the professional staff numbers about 100. The Division's research programme ranges over the field of entomological research with particular emphasis at the present time in the fields of population dynamics and ecology, physiology and biochemistry, taxonomy, and biological control. Many studies are in progress on methods of insect control that do not rely upon the use of insecticides. There are excellent facilities for a wide range of research activities.

DUTIES The appointee will be required to carry out research within the broad field of biological control of weed and insect pests.

QUALIFICATIONS Applicants should have a Ph.D. degree or post-graduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability.

SALARY Depending upon qualifications and experience, the appointment will be made within the salary range of Research Scientist, $A6,139–$A7,789 p.a., or Senior Research Scientist, $A8,105–$A9,448 p.a. Salary rates for women are $A428 p.a. less than the corresponding rates for men. Promotion within CSIRO to a higher classification is determined by merit.

CONDITIONS The duration of the appointment will be determined in consultation with the successful candidate; some applicants may prefer a fixed term appointment for three years. The appointment will be conditional upon passing a medical examination and an initial probationary period of twelve months may be specified. An indefinite appointment carries with it Commonwealth Superannuation Fund or Provident Account privileges. Further details supplied on application.

Applications, (quoting Appointment No: 180/538), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach:

Mr. R. F. Turnbull,
Chief Scientific Liaison Officer,
Australian Scientific Liaison Office,
64-78 Kingsway, LONDON, WC2B 6BD

by the *15th May, 1970.*

Applications in U.S.A. and Canada should be sent to The Scientific Attaché, Australian Embassy, 1601 Massachusetts Ave. NW, WASHINGTON DC 20036.

(1551)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF CHEMICAL ENGINEERING

CHEMICAL TECHNICIAN

required, preferably with H.N.C. to work within a research group investigating polymers. The work requires an interest in analytical and preparative chemistry, and the successful candidate must be able to work without close supervision. The laboratories are modern and well equipped, and present an opportunity to specialise further and gain experience in other techniques, such as Electron Microscopy.

Salary at present under review but currently on a scale rising to £1,127 per annum.

Please apply to: Dr. G. F. Freeguard,
Department of Chemical Engineering,
The University, Nottingham

giving details of career to date and names and addresses of two referees. (1538)

UNIVERSITY OF MANCHESTER

DEPARTMENT OF ANATOMY AND

MANCHESTER ROYAL EYE HOSPITAL

Applications invited from candidates with medical qualifications registrable in this country for two joint posts of Temporary Lecturer in Anatomy/Senior House Officer in Ophthalmology. The persons appointed will work in the University Department of Anatomy and in the Eye Hospital, spending approximately half their time on work in each department. Experience in Ophthalmology is desirable; candidates working for Primary F.R.C.S. acceptable. Salary range per annum : £1,570 to £1,790. Initial appointment for one year commencing October 1, 1970, but renewable for a second year.

Particulars and application forms (returnable by April 29) from the Registrar, The University, Manchester, M13 9PL. Quote Ref : 64/70/Na. (1477)

SK&F

PHYSICAL ORGANIC CHEMIST

Smith Kline & French Laboratories Ltd. is the U.K. Division of a leading international pharmaceutical group. Our Research Laboratories and Head Office are located in Welwyn Garden City.

A vacancy has arisen for a Ph.D. Chemist, with several years experience, to join the Physical Organic Chemistry Department of the Research Institute. The successful applicant will supervise the IR/UV Laboratory, and he will be required to work closely with our medicinal Chemists to provide physico-chemical support using a variety of techniques. Experience in the measurement of dissociation constants and partition ratios, as well as a knowledge of thermodynamics and statistical mechanics would be desirable. Some experience in the use of computers would be an added recommendation.

Fringe benefits include annual bonus, non-contributory pension and life assurance schemes, and subsidized staff restaurant. Full relocation expenses will be paid to applicants joining this successful organization.

Please write or telephone for an application form to.

C. J. Baron, Personnel Officer,
Smith Kline & French Laboratories Ltd.,
Mundells, Welwyn Garden City, Herts.
Telephone: Welwyn Garden 25111—Ext 342.

(1568)

INSTITUTE OF OCCUPATIONAL MEDICINE EDINBURGH

ERGONOMIST

A graduate ergonomist is required in the Physiology Branch of the Institute of Occupational Medicine, Edinburgh, which is associated with the University of Edinburgh.

The successful candidate will be employed by the National Coal Board but stationed at the Institute.

The successful candidate will assist a senior ergonomist at the Institute in the investigation of problems connected with the Coal Industry. Field work at various coalfields throughout the country will be undertaken.

Salary will be within ranges extending from £1,160 to £2,335 according to qualifications and experience.

Applications, stating age, qualifications, experience etc., should be sent to the **Staff Manager, National Coal Board, Lauriston House, 80 Lauriston Place, Edinburgh,** before 25th April, 1970, quoting Reference 45/70.

(1545)

AUSTRALIAN NATIONAL UNIVERSITY

INSTITUTE OF ADVANCED STUDIES THE RESEARCH SCHOOL OF PHYSICAL SCIENCES

Director: Professor Sir Ernest Titterton, C.M.G., F.A.A.

CHAIR OF APPLIED MATHEMATICS

Applications are invited for appointment as the Foundation Professor and Head of the new Department of Applied Mathematics, Research School of Physical Sciences.

The new Department of Applied Mathematics will join the six existing Departments (Astronomy, Engineering Physics, Geophysics and Geochemistry, Pure Mathematics, Nuclear Physics, Theoretical Physics) and two Units (Diffusion Research Unit and Electron and Ion Diffusion Unit) within the Research School of Physical Sciences. An eighth Department—Solid State Physics—will be established within the next year. The School of General Studies of the University has Departments of Pure Mathematics, Applied Mathematics and Theoretical Physics.

The new Department will be developed over a period of two to three years to an ultimate staffing level of twelve (including academic staff), with up to ten research students supporting its work. The Head of the Department will be responsible for choosing the staff and developing a research programme in chosen areas of Applied Mathematics. However, it is hoped that there will be a strong link between some of the Department's work and fields of experimental work already under way in Canberra, either within the University (which, in addition to Physics, has Schools of Biological, Chemical, Medical and Social Sciences) or in other research organisations such as the C.S.I.R.O.

The normal salary for a Head of a Department is $A13,000 per annum and there is entitlement to one year's study leave on full pay, plus a grant of not more than $A3,200 towards expenses in every four years. Salaries are currently under review and improvements are expected. Superannuation is on the F.S.S.U. pattern, with supplementary benefits. Reasonable travel and appointment expenses will be paid and assistance provided with housing.

Further information about the position and a summary of conditions of appointment of academic staff may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London, W.C.1.

Applications close on **May 15, 1970.**

(1493)

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Lecturer in Veterinary Pathology.

The successful applicant will participate in the teaching of Morbid Anatomy, Histopathology and Histochemistry, and will also be expected to engage in research in these subjects. There are good facilities available for research.

Initial salary will be within the range £1,240 to £2,850 per annum, according to qualifications and experience.

Applications, stating age, qualifications and experience, together with the names of three referees, should be received not later than May 2, 1970, by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Please quote ref. RV/5790/N.

(1454)

G.K. BUREAU

Offer a Free Personal Service to Scientific and Technical staff in the following fields: Applied Biology, Chemistry, Physics, Metallurgy, Electronics, Engineering, Geology, etc.

Ring or write 17 Shaftesbury Avenue, W.1. 01-734 7232. Interviews by appointment only.

RECENT SCIENTIFIC AND TECHNICAL BOOKS xxv

Nature in North America: The *Nature* office in Washington DC has opened and contributors in the United States and Canada are invited to submit manuscripts for publication either to the address given below or to the present London office. The intention is that each office will be able to answer inquiries about all manuscripts and other matters. This is one of several steps by which it is hoped to provide a better service for readers and contributors.

London Office
4 Little Essex Street,
London WC2.

Why Pye Chromatography

The crowning success in the design of complex analytical instruments is the achievement of simplicity. You will find it in Pye Analytical Gas Chromatographs.
Take the simple, functional glass-to-metal seal, for example. It makes column changing quicker and easier, improves sensitivity by reducing contamination of the gas stream and pushes the effective working temperature of glass columns up to 350°C.
Pye gas chromatographs are easy to use because we design them to give you what you want in instrumentation – accuracy, reproducibility, flexibility, simplicity.
Two systems are available, both with a wide range of optional modules—
The Pye Series 104 Chromatograph for research or routine work, with many accessories including wide-range amplifier and auto-solids injection . . . and the Pye Model R Research Chromatograph with modular column oven, unique "total-loss" cooling system and simultaneous two column multi-detector operation.
To learn more about Pye chromatography including industrial instrumentation, the GM60 Gas Chromatograph-Mass Spectrometer system and the DP90 Dataco computerised chromatograph system, write or 'phone today.

PHYSICAL SCIENCES

Quasars—Relation between linear polarization and redshift—CONWAY and GILBERT (Jodrell Bank) 332

X-ray astronomy—Upper limit for γ-ray point source—NARANAN (Tata Institute) 333

Selenology—Anorthosites on the Earth and Moon—WINDLEY (Leicester) 333

Moon—Comments on the seismic data—PANDIT and TOZER (Toronto) 335

Quasars—Gravitational lenses and quasars—BARNOTHY and BARNOTHY (Illinois) 335

NP 0532—Explanation of odd behaviour—CHIUDERI and OCCHIONERO (NASA) 337

Solar system—Possible clue to early evolution—MABUCHI and MASUDA (Tokyo) 338

Gravitation—Generalized Hoyle–Narlikar particle theory—McINTOSH (New England) 339

Geophysics—Interrelationship of the gravity and geomagnetic fields—KHAN and WOOLLARD (Hawaii) 340

—Earth normal mode spectrum from 6·5 magnitude earthquake—BLOCK, DRATLER and MOORE (California) 343

—Diamonds concentrated in the upper mantle?—LANG (Bristol) 345

Geomorphology—Why seashore boulders fit together—HILLS (Melbourne) 345

Estuaries—Buried channels in the Thames—D'OLIER and MADDRELL (Sir John Cass College) 347

Mineralogy—Precipitation of metastable carbonate phases from seawater—TOWE and MALONE (Smithsonian Institution) 348

Materials—Polymer microdefects as the centres of destructive cracks induced by laser irradiation—AGRANAT, CHERNYAVSKY, NOVIKOV, SALUENYA, YAMPOLSKY and YUDIN (USSR Academy of Sciences) 349

Reactors—"Dust curtain" in gaseous core nuclear reactors for rockets—LIU (Michigan) 351

Drag—Effects of shear treatment on drag-reducing polymer solutions and fibre suspensions—ELLIS (Admiralty Underwater Weapons Establishment) 352

Lasers—Energy resonances between molecular species in CO_2 gas lasers—NICHOLLS (York University, Toronto) 353

BIOLOGICAL SCIENCES

Haemoglobin—α-Chain duplication in Barbary sheep—WILSON, WRIGHTSTONE and HUISMAN (Medical College of Georgia and VA Hospital, Augusta) 354

Transferrin—Test of selective release of iron from A and B binding sites—CHERNELCH (General Hospital, Maribor) and BROWN (Washington) 356

IgG fragments—Fc crystals in high yield—SANDERSON and LANNING (Queen Victoria Hospital, East Grinstead) 356

Peptide bond formation—Use of phenylalanyl-tRNA - guanosine - **5′** - triphosphate - $\mathrm{TI_u}$ complex—SHOREY, RAVEL and SHIVE (Texas) 358

Thyroid hormones—Production of antibodies to triiodothyronine—BROWN, EKINS, ELLIS and REITH (London) 359

Histamine—Biologically active antibodies to albumin complex—DAVIS and MEADE (Arthur D. Little Inc.) 360

Interferon—Cross-reactivity in avian systems indicates incomplete species specificity—MOEHRING and STINEBRING (Vermont) 360

Polyanions and infection—Pyran and poly I · poly C protect mice—REMINGTON and MERIGAN (Stanford) 361

Poly I · poly C—Induced resistance to TMV infection in plants—STEIN and LOEBENSTEIN (Volcani Institute of Agricultural Research) 363

Polynucleotides—Increase in antiviral activity by thermal activation—DE CLERCQ, WELLS and MERIGAN (Stanford and Wisconsin) 364

Transplant survival—Anti HL-A2 inhibitor in normal human serum—VAN ROOD, VAN LEEUWEN and VAN SANTEN (University Hospital, Leyden) 366

Xg locus—Failure to detect inactivation in females with chronic myelocytic leukaemia — FIALKOW, LISKER, GIBLETT and ZAVALA (Washington and Instituto Nacional de la Nutricion, Mexico) 367

Immunosuppression and cancer — Metastatic growth favoured by antilymphocyte serum—GERSHON (Yale) and CARTER (Chester Beatty Research Institute) 368

Muscular contraction—Impermanence of depolarization by acetylcholine—MAGAZANIK and NASLEDOV (USSR Academy of Sciences) 370

Infant autism—Abnormalities in platelet serotonin—BOULLIN, COLEMAN and O'BRIEN (Children's Hospital of Washington) 371

Chlorpromazine — Quantitative determination of metabolites using dansyl chloride—KAUL, CONWAY and CLARK (Oklahoma) 372

Neurophysiology—Allylglycine inhibits Mauthner cells—ROPER (London) 373

Memory—Recall of item and order information and presentation rate—MATTHEWS and HENDERSON (Guelph) 374

Wheat cytogenetics—Homoeologous meiotic chromosome pairing in which 5*B* is replaced by an alien homoeologue—CHAPMAN and RILEY (Plant Breeding Institute, Cambridge) 376

Gene damage—Sunlight-induced killing in the yeast *Saccharomyces cerevisiae*—RESNICK (MRC) 377

NATURE Volume 226 APRIL 25, 1970

Is there a Future for Science in the United States?

THE foolish muddle in the United States about funds for academic science in the coming financial year is bound to leave a deep scar. Even if, against the odds, the National Science Foundation emerges by July with more money than it was allowed to ask for—$50 million more if Senator Edward Kennedy has his way (see page 307)—and even if the Administration agrees to spend the extra, there will not be enough to go round. So much is already clear. The whole of $50 million would be needed simply to keep alive the projects being dropped by the Department of Defense. There would be nothing left over to support projects abandoned by other agencies—the Princeton–Pennsylvania accelerator which the Atomic Energy Commission proposes to abandon, for example, and the projects in organic chemistry of which the National Institutes of Health have washed their hands. And, however generous Congress may think it safe to be, there is unlikely to be money to meet the needs of those who responded four or five years ago to the cry for more graduate students, and who are now ready to set up on their own. Moreover, there is no chance of funds for making good some of the glaring deficiencies which have been allowed to accumulate—the scandalous shortage of radio telescopes, for example. To be sure, it has become fashionable to say that science ought to be bent to more practical tasks, but there is very little to suggest how this can best be done and not a shred of evidence to show that damaging the splendid structure of American science which has been built up in the past 25 years will help. The issue is whether the United States shall remain the pacemaker of scientific discovery which it has become.

To worry about the budget for the next twelve months is therefore less important than to be alarmed for the more distant future. Experience in the past few years suggests that trouble about the budget of the National Science Foundation will be an annual occurrence. The most distressing feature of this year's fiasco is the Administration's indifference to the consequences of its decisions. The notion that future generations of graduate students should be supported by loans, supposedly the origin of the decision that the National Science Foundation should not make traineeship awards after this September, will have all kinds of apparently unexpected results—it will tend to concentrate graduate education in the stronger departments, and will tempt those who apply for research grants to include graduate students on their payrolls, thus further reducing the independence of students. After all the care that has been spent in past decades on the encouragement of graduate education, it is almost unthinkable that the Administration should have foisted this principle on the system in such an unreflective way. So it is time to think of structural changes that may insure against a repetition of these follies.

Where should reconstruction begin? The Federal Government must first make up its mind what it hopes to gain from its support of basic research in universities, directly through research grants and by the support of graduate students. To begin with, it has never acknowledged with sufficient generosity that federal spending is necessary if higher education is to flourish. The first report of the National Science Board in January 1969, which eloquently argued the case for a growing commitment to graduate education, has been studiously ignored. The $1,000 million or so of federal research money which finds its way directly to the universities each year is, however, an indispensable assurance of the quality of university education, undergraduate and graduate. The Federal Government has also in the past been concerned with the importance of discovery, and the way in which American universities have helped to break new ground throughout science in the years since the first Sputniks appeared is a moving illustration of the power of pure reason. Is all this to be thrown away now that the answer to the Sputniks—the flight of Apollo 11 last year—has been produced? And has the Federal Government forgotten how much the vigour of some of the mission agencies since the Second World War has depended on the work of scientists at universities? Some may think that short commons will force the goose to lay more golden eggs, but it is more likely that the treatment may prevent it from laying altogether.

From these principles follow several simple rules. First, continuity is essential. President Nixon himself was fond of saying, during his election campaign, that "you can't turn science off and on like a faucet". Discontinuity saps the morale and turns away intending scientists. It also dissipates the momentum of discovery—it is hard to turn intellectual creativity off and on. But discontinuities are also wasteful—the proposals for the coming financial year will entail a great many profligacies—the closing down of the Princeton accelerator is but one illustration of the wanton discarding of valuable resources.

The second rule which must somehow be accepted both by the Administration and by Congress is that the scale of support for university research should be determined partly by decisions about the scale and quality of higher education and partly by judgments about the development of science as such. If, for example, the objective is to improve the standing of the weaker universities, ways of geographically spreading out research funds should be sought. If there seems to be a need to encourage research in a new field —teratology, perhaps, with all the excitement about the potentially harmful consequences of food additives —then pump-priming must be a public expense.

It also follows that in the allocation of research money to different areas of research, a balance should be struck on scientific and not administrative grounds. One of the defects of the present arrangements is that large parts of the spending on basic research are not subjected to the thorough analysis which, for housekeeping reasons, the National Science Foundation and the National Institutes of Health consider necessary. High energy physics is isolated and insulated beneath the umbrella of the Atomic Energy Commission. Much of what American universities do in materials science —there is probably too little of it—is supported by the Department of Defense. And, however great the diligence with which the National Aeronautics and Space Administration sets out to examine proposals for research in astronomy and the physics of the solar system, these are not weighed against more modest land-based proposals intended to accomplish the same ends. Thus it is doubtful whether NASA would have been about to build the X-ray telescope due to be launched in the first manned astronomical satellite if it had had to apply to the National Science Foundation for the money. Anomalies like this are by themselves sufficient cause for welcoming the spirit of the Mansfield amendment to the current defence appropriation— the principle should be that the mission agencies support basic research only when there are special reasons why this is essential. In short, it is now time to abandon the plurality of agencies which, in the fifties and sixties, gave scientists the illusion that there was no shortage of money.

A further corollary is that there should be a greater degree of independence for whatever agencies are responsible for spending federal money on scientific research and higher education. To be sure, in the last resort the government must decide how much money there is to spend—that is inescapable. But the people responsible should then be free to use the intricate system of advisory committees which they have developed to decide precisely how funds shall be allocated. Although the National Science Foundation has the theoretical benefit of not having to justify its budget item by item to Congress, the Bureau of the Budget seems to use a remarkably fine-tooth comb. But why should the Administration keep a dog and then bark itself (through the Bureau of the Budget) ? It would be better for everybody's sake, for example, if the National Science Foundation were to decide whether to pay stipends to graduate students directly or let them be added to research grants. And why should external influences be so powerful in deciding how much is spent on radio telescopes ? One of the defects of the present interaction between the Administration and the agencies responsible for science is that the little money there is may be spent less well than possible. Another is that the agencies concerned do not develop the general concern for the forward planning of the scientific enterprise that should be central to their functions. Then the general sense of fickleness which runs through a great deal of what passes for science policy serves powerfully to discourage those who do the donkey work on the advisory committees and their constituents.

So what is to be done ? The best hope is that the new Administration's concern for organization will provide an opportunity for putting the financing of scientific research on a more secure foundation. The Ash Commission will be making recommendations to the President throughout this year—proposals on the agencies concerned with the environment will probably go forward before the end of April, for example. Although there are some who say that the problems of the National Science Foundation would disappear if only its budget were twice as large, mere money will not avoid the structural defects in the present system. To be sure, the National Science Foundation should be at the centre of any reorganization, but the objective should be to add not to its budget but to its responsibilities. Thus it would be sensible to transfer from the Atomic Energy Commission responsibility for high-energy physics, together with some of the laboratories involved. Some parts of the work done by the National Institutes of Health should also properly belong to an agency concerned with the support of university research. And there is a case for channelling external advice on the expenditure of NASA and the DOD on university research through the same advisory committees.

Simple repackaging, however, is not enough—it is also necessary to provide a stronger agency with a self-renewing sense of purpose. Is it entirely beyond reason that there should be an organization with broad responsibility for the development of the understanding and the skill which the modern world increasingly demands ? This, after all, is what the National Science Foundation has been trying to do on its perpetual shoestring. The National Institutes of Health have done equally valiant work in medical education. Research, training and curriculum development have gone hand in hand. It may now be opportune to broaden the scope of this work. And this is a cause for which a properly chosen board would be able to fight coherently—and publicly. To be sure, there are many congressional committees and interests outside Congress that would resist the notion, but that is no reason for doing nothing.

In these discussions, the Office of Science and Technology seems increasingly irrelevant. That may be inevitable, for the days are probably gone when the presence of a scientific adviser at the White House could give the scientific community a sense of being properly represented at the centre of power. For one thing, times have changed. The scientific community as such is now less well placed to give crucial advice on urgent problems than in the fifties; it can expect fewer favours in return. But the office was lent special lustre by those who first occupied it and by their personal influence with the president of the day. It is no longer safe to rely on the good chance that the incumbent will be at once able and influential, but in any case the prestige of the office has in the past two years been severely damaged by the trouble over the budget of the National Science Foundation. In the circumstances, it would be better for the scientific community as a whole that there should be a strong organization built around the National Science Foundation, and free to speak out when policies seem misconceived, than that there should be an Office of Science and Technology at the White House. That could be a valuable counter in any bargaining on organization there may be.

Pull Up More Weeds

THE events leading to the decision last week in the United States to restrict the use of the herbicide 2,4,5-T, reported in their tedious detail on page 309, embody important lessons for those anxious to see emerge more deliberate procedures for the regulation of chemicals in the environment. From this point of view, the notoriety that 2,4,5-T has acquired through its use in the attempted defoliation of large areas of Vietnam is almost irrelevant, even though there will be some relief that the United States Army will now restrict the use of 2,4,5-T (but not necessarily of the other herbicides used for defoliation). The case against the use of herbicides for defoliation has quite properly been based on the doubt which there must be about the ecological damage which may be done by large-scale destruction of vegetation. Even hawks should be asking what purpose would be served by winning the war by methods which might make it necessary to wait for decades to see the land recover its capacity to bear crops. In narrower terms, there are also serious doubts about the tactical effectiveness of defoliation that should long since have given the US Army pause in its policy of defoliation—is a farmer whose crops have been destroyed more, or less, likely to join the Viet Cong ? The implications of questions like these for what happens in Vietnam remain important, but they are separate from the issues now raised by the restrictions on the civil uses of 2,4,5-T.

It is only fair to acknowledge that a good deal of present concern for the biological consequences of trace amounts of organic chemicals in the environment stems almost directly from the way in which chromatography in its several versions has made possible the detection of some of these materials. To say that is not to complain that chromatography has made life more difficult, of course, but merely to suggest that a new range of problems has been brought within reach of tackling. It is also proper to admit that several recent scares have drawn attention to previously unsuspected sources of biological hazard—the thalidomide incidents in Britain and Germany have cast a long shadow. What is happening now, belatedly perhaps, is that regulatory authorities are being forced, either by their own inclinations or by pressure from outside, to re-examine old decisions to permit the public use of various chemicals, food additives, herbicides, insecticides and the like. That such a process is under way should not be regarded as a sign that strange chemicals now assault the environment to such a dangerous extent that extraordinary steps have to be taken to avoid trouble—it is equally fair to say that opportunities have now been provided that will ensure a safer environment. The way in which specific hazards of some kinds of factory employment have been eliminated in the past half century by formal regulation is a proof that the process is continuous. It would be in everybody's interest if there could be a more common understanding of how these matters should be organized.

First, panic and the appearance of panic can and should be avoided. The way in which the Secretary for Health, Education and Welfare in the United States decided last October to take cyclamates off the market has diminished the credibility of those public officials whose job it is to regulate chemical hazards. The circumstances leading to the banning last week of the herbicide 2,4,5-T are not much better. Everybody knows that experimental data whose significance (in the strict sense) is worked out over the weekend tend to be made too much of. As things are, nobody can be quite sure what weight to give to the different pieces of evidence upon which the decision to restrict the use of 2,4,5-T is based. It looks as if the experiments which have been carried out show that in mice, but not in rats, pure 2,4,5-T is teratogenic. Everybody would wish, however, for more extensive experiment and for more time to consider the results. The fact that there is at present a sense among politicians that the public wants quick action should not blind them to the need that this action should be deliberate. The way in which the Department of Health, Education and Welfare has had to beat a partial retreat from its original position on cyclamates should have been a reminder of what may happen when decisions are made too quickly.

But how are decisions about the safety of chemical contaminants to be arrived at ? The present convention is that the politician responsible for the appropriate department of state, advised by his officials, will shoulder this responsibility. The trouble here is that the data frequently do not lend themselves to unambiguous interpretation. Deciding what to make of a series of unrelated animal experiments with unfamiliar chemicals in small quantities is a little like the familiar problem in the physical sciences of trying to decide which of several alternative values for a constant of nature is most to be trusted. In those relatively simple circumstances, decisions are hard to make and time-consuming. Moreover, the process is one of scholarship, not political decision-making, so is there not a case for letting the crucial assessment of the risks involved be decided by something like the familiar academic process in which a group of people worries out what seems to be the truth and then lets the rest of the scientific community say whether the diagnosis makes sense? The politicians may say that the public will not wait that long, but this is surely mistaken. There is no evidence that the imperfectly assessed hazards of chemicals recently thought safe are so conspicuous that damage will be done if decisions are postponed for a few months.

Assessments like these will, of course, take time and skill at present in short supply, and one of the most striking lessons of the public inquiry into the use of 2,4,5-T is that there is an urgent need for more professional research of a kind which can help to define teratological and mutagenic hazards. Since in the long run the best hope is that better understanding in embryology and carcinogenesis will help to identify trouble in advance, the emphasis should be on university research in collaboration with more fundamental studies, and not on the attempt to win quick answers by animal experiments blindly carried out. This is an urgent need, and there is, unhappily, very little sign that the governments anxious to respond to popular feeling about contaminating chemicals are prepared to spend the trouble and the money.

The implications of a more active policy by governments towards contaminating chemicals for the relationship between governments and industry are potentially important and should also be thought of in advance. The Mrak commission on pesticides in the United States estimated last year that the cost of bringing a new agricultural chemical to the market is about $5 million, and it is plain that manufacturers will be less willing to spend money on research and development if the chances of being able to market an otherwise successful product are restricted by the discovery of some unwelcome and possibly unexpected side effect. Moreover, it is anomalous that most governments—certainly the British and the American—should expect manufacturers to pay for the cost of the tests necessary to demonstrate that a new chemical can be safely used. So is there not a case for asking that some part of the increasingly onerous cost of testing should be borne by the central government? This is not so much a matter of equity as of making sure that the inventiveness of the chemical industry is not stifled to a degree that will limit its social value. To be sure, where proprietary materials are involved, other issues of principle arise. Governments might find it necessary to ask for a transferable patent right for compounds tested with public money. Whatever the pitfalls, however, governments wishing to claim a good reputation on environmental chemicals had better face up to problems like these.

Should governments, however, operate independently? It is conventional to pay lip service to the view that international collaboration is essential. In practice, precious little has been done. Even in the exchange of information about chemicals in the environment, good intentions are victims of haste like that which led to the restriction on 2,4,5-T last week. The truth seems to be that governments and their officials do not believe that international collaboration has anything of value to offer. The Mrak commission which reported in the United States last December was in general a monument of good sense, which nevertheless finished its lukewarm recommendation on international action with the meaningless suggestion that "the US government should assume leadership in studying the inherent health hazards of pesticide usage and cooperate in the training of technical personnel from other countries". Is this the best that an otherwise enlightened committee can suggest? Is there some reason why the process of testing the safety of novel compounds cannot literally be shared within the scientific community? Why should not organizations such as the World Health Organization play a part in the administration of these schemes? For all the drama of the announcement about herbicides last week, the wisdom of the decision taken remains in doubt—it may yet turn out that the Dow Company's case is upheld by further work—but the need for better machinery has been demonstrated for all to see.

---

100 Years Ago

It is no longer a secret, that wherever a persistent warfare is carried on against small birds—against martins, blackbirds, sparrows, larks, &c.—vegetable life is sure to suffer. In the Isle of Bourbon, as M. Michelet tells us, the martin was exterminated, and a plague of grasshoppers followed; in Hungary, the sparrow was proscribed, until this valiant militia of the fields had to be recalled; in the neighbourhood of Rouen, the blackbird was shot down without mercy, and many a meadow's turf could be rolled up like a carpet; and in this country we had, until lately, our sparrow clubs, which paid for little victims at so many a dozen, just as two or three hundred years ago some of our pious churchwardens used to purchase hedgehogs of truant schoolboys in the rural districts, a lamentable increase of pestiferous insects being the consequence. The Rev. Charles Kingsley gives us a more recent example. In Trinidad, the free negro has been banging away at the small birds, partly for his own pleasure, and partly to supply the London markets and our ladies' hats. What has been the consequence? "Already the turf of the savannah, or public park, close by, is being destroyed by hordes of mole-crickets, almost exactly like (strange to say) those of our old English meadows; and unless something is done to save the birds, the canes and other crops will surely suffer in their turn.

From Nature, **1**, 648, *April* 28, 1870.

OLD WORLD

MOLECULAR BIOLOGY

EMBO goes Critical

Molecular biology in Europe has just taken another step forward with the establishment of the European Conference on Molecular Biology. Twelve states (Austria, Denmark, France, Greece, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, Britain and West Germany) have already joined the organization; Israel is also to be a member and the Fonds National Belge will assume the obligations which would have fallen on Belgium had it joined. Financial contributions from member states will be assessed on the basis of net national revenue. The budget for 1970 amounts to $632,000 and expenditure for 1971 is planned to be about $1 million. EMBO, which has hitherto been supported largely by the Volkswagen foundation, will now receive its funds from the ECMB.

The conference is normally to meet once each year, but because it has only just been established and the first plenary session held, it is due to meet again in November. The project to establish a European Laboratory for Molecular Biology is gathering momentum, and EMBO has recently revised its earlier proposals. The ECMB has set up a working group to study the revised proposals, and this is to meet in September and report to the subsequent meeting of the ECMB.

The underlying philosophy of the EMBO proposals remains largely unaltered. There will be only a small number of permanent scientific staff; the laboratory will place strong emphasis on the advanced teaching of postdoctoral fellows by conducting courses and workshops after the example of Cold Spring Harbor in the United States; and there will be "project space" available for groups which wish to use special facilities for particular experiments. The plan differs, however, in emphasis and in scope from its predecessor. The first plan was to establish a laboratory which would grow over a period of eight years to about 260 scientists and costing some $18 million. The laboratory would have an annual budget of about $10 million. The revised plan is more modest, and demands only an initial laboratory of about sixty scientists, with an initial cost of about $5 million and an annual budget of $4 million. Questions of expansion are left to future negotiations.

Rather more detailed proposals are now made for the research programme, although EMBO acknowledges that these are examples of the nature of the research which may be carried out rather than firm intentions. Both the present trends of molecular biology are reflected in these suggestions. The reductionist approach which aims to explain biological functions in terms of the physicochemical properties of molecules is represented by proposals which include the study of macromolecular assemblies such as membranes and ribosomes. The second approach, the application of the concepts and methods of molecular biology to more complex systems, is shown in proposals for research into the cell genetics of mouse and man and for a genetic study of the structure and function of membranes. The laboratory would also have as a major task the development of the sophisticated instrumentation which is likely to be necessary for future experiments in molecular biology.

The report of the ECMB working group on these proposals is the critical stage in the development of an EMBO laboratory. The omens are good that the group will agree on the establishment of such a laboratory, for of the fourteen countries of the ECMB, eleven have expressed general approval and only three remain neutral. There remains the danger, however, that if agreement is reached, there will be dispute as to which country is to house the laboratory. EMBO itself has suggested Geneva, where CERN is already located, and offers of sites have come from Austria, France and Italy. Other countries are also rumoured to be considering making bids to acquire the laboratory. But even if full agreement is reached in November, it will still be some considerable time before a laboratory is established. Design and building are likely to take at least three years, so that the laboratory would not be able to commence its activities before 1973 and would not be fully functional until perhaps 1975. A glimmer of hope for an earlier establishment, however, may be found in the suggestion that temporary accommodation may be sought to enable an EMBO laboratory to start work within the next couple of years.

PARTICLE ACCELERATORS

Sights Lowered at CERN

Just as hope was receding that the 300 GeV accelerator project would ever get off the ground, an entirely new plan was put forward by Dr Adams's group at CERN last week which seems to have most of the ingredients of a working compromise. The idea is to start off by building a machine to produce particles of 150 GeV, but to use what is known as the "missing magnet" design to allow the maximum energy to be raised at a later date to 300 GeV or 600 GeV, as physics and the economic circumstances dictate. The initial outlay for the 150 GeV accelerator would be a third less than the £150 million budgeted for the former 300 GeV project.

In the new proposals, which seem to be intended as a sort of CERN green paper, the ring of 2·4 km diameter suggested for the old 300 GeV scheme would be replaced by one of 1·8 km diameter which could be fitted into the existing CERN-Meyrin site near Geneva. This would avoid the wrangle over a site which jeopardized the earlier project. If superconducting magnets become a practical reality for synchrotrons within the next ten years, as many people believe, additional magnets could then be added to the ring and the conventional magnets replaced to produce fields capable of accelerating protons up to 600 GeV or even 800 GeV.

In the light of the new proposals, it seems that the way the original 300 GeV scheme was formulated may have been a tactical error. For one thing, it left little scope for incorporating significant advances in magnet technology and it presented governments with a single investment decision of considerable magnitude. To be sure, the advantage of a fixed energy machine is that the design can be optimized throughout for the peak energy, but with so many other variables in the equation this may well have been too blinkered an approach.

Of the three types of accelerator that Dr Adams's group could have considered, the missing magnet design is in a sense the obvious choice. It is the most technologically flexible, which is important if the machine is to be extended in energy beyond the limit of the 200 GeV Batavia accelerator in the United States, which is already nearing completion.

Moreover, the decision to boost the maximum energy by a factor of four or more can be left to depend on the results of the first round of experiments. In the "missing power" type of machine as at Batavia or the fixed energy type as in the original CERN proposals the options are far more limited, although the Batavia accelerator can, of course, be extended up to 400 GeV if required.

The inspiration for the new proposals no doubt derived from the rapid progress in developing superconducting magnets, notably at the Rutherford High Energy Laboratory in Berkshire.

GENERATORS

Breakdown in Detail

LACK of attention to detail in the design of 500 MW generating units was largely responsible for the plant breakdowns that led to voltage reductions last December. This verdict of the Select Committee on Science and Technology is clearly spelled out in the committee's first report to Parliament this session (HMSO, 20p) and follows chiefly from evidence given to the Select Committee by representatives of the Central Electricity Generating Board (see *Nature*, **225**, 496; 1970). Other faults exposed in the report are hairline cracks and defective welds in the boilers and "malicious damage".

The Select Committee began its investigation after the Minister of Technology had said in a written reply that he thought an official inquiry would not help. But Mr Arthur Palmer's committee decided that a brief fact-finding inquiry was in order and, although the report can find little room for major recommendations, it tells a sorry tale of annoying faults that eventually caused sixteen 500 MW generators to fail, and reduced power in the grid on five separate occasions.

The only remedies that the committee can suggest are that the CEGB should place design contracts with boilermakers before the final contracts for steam-raising plant are finalized, and that every effort should be made to test plant before it actually generates electricity into the national grid. Placing design contracts in this manner will, in the committee's opinion, encourage the setting up of strong design teams, who could be called on whenever precise data are needed for development work. As far as testing is concerned, however, the committee recognizes that little can be done to test large components on full load before they are installed in power stations, but it welcomes the plans for wider testing of the 660 MW sets which are now being developed.

Evidence submitted to the Select Committee by Mr E. S. Booth, the CEGB's member for engineering, also pointed to the possibility that some of the failures were caused by tools and other foreign bodies being deliberately left in vital parts of equipment. But both he and Sir Stanley Brown, chairman of the CEGB, said that site discipline is an intractable problem and, although methods have now been devised for detecting foreign bodies in plant, little can be done to prevent such occurrences.

The other major headache of the CEGB—corrosion of mild steel nuts and bolts in magnox reactors—also came under the Select Committee's scrutiny. It seems that the operating temperatures have now been reduced in all the affected reactors, and output has been cut back by a total of about 500 MW. But despite these setbacks, the reactors should enjoy at least their economic life. The committee believes, with the benefit of hindsight, that nuclear engineering teams need strengthening by people interested in corrosion problems of all kinds, and with the technical competence to handle them, and it also recommends that all items of equipment whose corrosion properties cannot be predicted with certainty should be removable.

HOVERTRAIN

New Track for Roskill

A NEW aspect to the discussion of where best to site London's third airport has been introduced by the recent disclosure that tests on a hovertrain capable of 300 miles per hour are to begin later this year on an experimental track just north of Cambridge. If successful, this would mean that an airport anywhere within a hundred mile radius of London could be reached in less than half an hour from the centre of the city. This may be the signal to banish the new airport once and for all from the heavily populated areas around London.

Engineers at Tracked Hovercraft Ltd, a subsidiary of the National Research Development Corporation, expect to carry out the first trial runs at the end of October 1970. The first three miles of track should be completed within the next two months and a further four miles will be constructed by the end of next year to permit the test vehicles to reach their cruising speed of 250 miles per hour.

The Roskill Commission investigating the question of London's third airport may now wish to extend the scope of its inquiry to include new technological developments. Tracked Hovercraft points out that the site at Foulness could be linked to the centre of London by a 25 minute hovertrain service to King's Cross, shuttling 100 passengers every two minutes in vehicles about the size of a standard railway carriage. The hovertrain would be driven by a linear induction motor, which is preferred to the French propeller driven model on the grounds of being quieter and more versatile.

Tests on the French hovertrain are already in progress at Orléans. With the foundations being laid now for a third airport at Paris, to the north of the city, the talk of a possible hovertrain link to the centre of Paris seems more than a flight of fancy. But although the technical feasibility of air cushion transportation is already well established, commercial viability seems to be a tougher proposition. The British Hovercraft Corporation, which makes the 150 ton SRN4 hovercraft, announced last week that it would be closing its factory at Itchen, Southampton, for lack of orders. The fifth model of the SRN4 is half complete and seems to be without a prospective buyer. Work on the smaller SRN6 and the 40 ton BH7 will be transferred to the company's main plant at Cowes.

GEODESY

Life without Echos

GEODESISTS are finding it hard going without the once familiar glow of the Echo satellites to illuminate their triangulations. Echo 1 re-entered the atmosphere on May 24, 1968, and Echo 2 followed a fraction more than a year later on June 7, 1969. During their lifetimes the Echo satellites—strongly reflecting balloons 41 metres in diameter—became well known around the world and, even, it is rumoured, venerated as gods in the African bush. With apparent magnitudes on the stellar scale of about 2·5, the satellites could easily be detected by the small cameras of the Western Europe satellite triangulation programme. (The larger the magnitude number the fainter is the object, and the limit for the eye is about magnitude six.) The aim of the programme is to obtain accurate locations for a number of stations in Europe relative to each other by photographing satellites against the background of stars. Geodesists are now having to make do with less bright satellites, and the situation was discussed at the Royal Society last week in a meeting of a subcommission of the International Association of Geodesy which deals with observations of artificial satellites from Western Europe.

As well as pressing for a third Echo satellite, the meeting appears to have backed another horse: the provision of more cameras able to track the faint satellites. Two of the balloon satellites which are at present being used for the programme—Explorers 19 and 39—are frequently too faint for the majority of European cameras. Last year's meeting of the subcommission in Paris initiated a test programme of observations of Explorer 39 beginning in May last year, and so far it appears that only five European countries have been able to obtain successful photographs. The reason is that the Explorer 39 balloon is only a few metres in diameter and that it is in an elliptical orbit so that its brightness, at best of magnitude 3·7, is variable.

A third balloon, the Pageos satellite consisting of a 30 metre diameter balloon of aluminized Mylar, is more easily visible at magnitude 1·6, but its orbit at a height of 4,000 km is less good for triangulation work over short European baselines than satellites at lower altitudes.

The subcommission is also looking forward to the launch of further satellites equipped with reflectors so that the more precise technique of laser ranging can be used. The next satellite in the series is Geos-C, expected to be launched in 1972, and the subcommission wants to see the laser method developed and used at European stations. At present satellite triangulation methods are giving accuracies in position of the order of 30 metres, less accurate than classical methods, but the hope is to improve the accuracy to about 3 metres using the standard photographic method, and to less than one metre using lasers.

But the subcommission is still hopeful of seeing another balloon satellite of the Echo type in a low altitude orbit, especially now that more countries are joining the programme with less powerful cameras.

Thirteen countries are participating in the triangulation programme with more than thirty cameras. In Britain, stations are at Malvern, operated by the Ordnance Survey, and at Earlyburn, near Edinburgh, operated by the Royal Observatory, Edinburgh. Both stations have successfully photographed Explorer 39 down to fainter than magnitude seven.

PRIVATE RESEARCH

Arthur D. Little's New Name

IN the long run the government's plan to set up a British Research and Development Corporation out of a handful of the research and development organizations of the Ministry of Technology may help the independent research institutes, according to Dr F. Neville Woodward, director of Inveresk Research International. Inveresk Research International is the new name for the Arthur D. Little Research Institute which has been operating since 1956 in laboratories near Edinburgh as an offshoot of Arthur D. Little Inc., of Cambridge, Massachusetts. The change comes about because the institute has bought out its financial involvement with the parent to become a wholly British-owned organization.

Announcing this in London last week, Dr Woodward said that the independent research institutes in Britain have nothing to fear if the proposed British Research and Development Corporation is set up. Although the corporation will be competing with the independent institutes for contract work from industry, Dr Woodward thought that in the long term the encouragement of sponsored research would be a good thing. The government plan, already criticized from several quarters, is that by 1975 the proposed corporation will be self-supporting with payments for work being done for industry accounting for one-third of the annual costs. Based on the Ministry of Technology estimates, this means that the present £10 million per annum earnings from industry by the government organizations involved in the plan will have to be doubled by 1975.

At present, Dr Woodward said, "the government is moving heaven and earth to find work for its employees in laboratories which we think ought to be run down". This is one of the reasons why Inveresk Research International, which specializes in pharmacology, polymers, membrane technology and organic semiconductors, now has no contracts with government departments. But Dr Woodward also said that the staff of the institute are not enthusiastic about taking on government work because the negotiations are frequently "painfully slow", and because the institute is often not told what becomes of the work which they have done. "It's like working in a vacuum," Dr Woodward said, "so we are far less enthusiastic about government work than we were in the past." In fact, roughly half of the income of Inveresk Research International comes from the pharmaceutical industry and twenty per cent of its work is for companies outside Britain.

COMPUTER POLICY

Choice of Hardware Too Wide

THE government should not contribute to the development of new computing machinery unless what emerges is a completely different type of computer which would fit in more closely with everyday work, the subcommittee of the Select Committee on Science and Technology, which is discussing how the British computer industry can best be encouraged, was told last week by Computeraid Ltd, a British computer service bureau. Last week the subcommittee heard evidence from Computeraid Ltd and from International Computing Services Ltd, a subsidiary of ICL.

In a memorandum the Computeraid representatives talked of the embarrassingly wide choice of computer hardware, and said that the proliferation of new hardware should be discouraged. Many small and medium-sized companies do not need the facilities of the third generation of computers, and the cost of the change-over from one generation of computers to another is extremely high. It may be that the government should set up disincentives to the introduction of new computers which do not show marked improvements over previous machines, the memorandum said.

Both organizations complained about the impact on the service bureaux of selective employment tax—the payroll tax which is designed to encourage the movement of labour to manufacturing industries by operating against the service industries. The Computeraid representatives thought that software houses and computer service organizations which might be expected to improve industrial efficiency ought not to be penalized by the selective employment tax. This view was supported by the memorandum from International Computing Services, which also agreed with Computeraid that the provision of computer programs through bureaux should also qualify for investment grants.

Following the attitude of the software houses at last week's meetings of the subcommittee, Computeraid thought that the government should look beyond its internal resources for computer services, as the United States government does, and that the government should consider asking outside organizations to run government computing facilities.

The service bureaux have also been pressing the Post Office to improve the data transmission facilities which are provided through the telephone system. The Computeraid memorandum said that unless the facilities provided by the Post Office are improved the use of on-line computing is unlikely to develop to its potential. The telephone system is, of course, optimized for speech, and in the opinion of Computeraid not enough effort is being devoted to networks suitable for data transmission. The bureaux are also concerned that the Post Office monopoly may interfere with the development of data communications.

POLLUTION

Fire without Smoke

FINANCIAL coercion and governmental control are the keynote of fifty proposals for attacking pollution in Britain, put forward this week in a report from the research department of the Labour Party. The measures suggested in this report cover the setting up of three new national agencies to deal with water supplies and sewage disposal, the dumping of wastes in the sea and the reclaiming of derelict land, and a plethora of taxes, levies and fines to put pressure on recalcitrant offenders, as well as a comprehensive family planning service under the National Health Service to grapple with what is the most basic problem of all. Those who argue that the cost to industry of implementing these schemes would be economically damaging ignore both the hidden costs of pollution and the fact that other countries face the same situation, according to the report (*Pollution and Our Environment*, 3*s*, from Transport House, London SW1).

The report, prepared for the National Conference of Labour Women to be held next month in Hastings, concentrates on declaring priorities rather than planning in detail. Its credo is that, if looking after the Earth is to be regarded as a social service, then the manufacturer and the consumer must accept the need to pay up just as they do for the other social services, whether the cost be direct (effluent treatment and the like) or indirect (the increased prices that will follow). "Pollution levies", too, could persuade people to buy or sell less damaging products, as in the case of household bituminous coal, which is claimed to account for 85 per cent of the smoke pollution in Britain; a price advantage for smokeless fuels would combine fruitfully with the stronger enforcement of the Clean Air Acts which the report also urges. But industry would have to take the brunt of the cost, helped on its way by an increase in the penalties for negligence, beyond the derisory fines which are often imposed now. Prosecutions for oil spillage off British shores in 1968, for example, resulted in fines that averaged £145.

A forceful argument for clean air is embodied in a retrospective survey from the Royal College of Physicians (*Air Pollution and Health*, Pitman, London, 30*s*). In 1952 some 4,000 people may have died because of a five-day London smog; the Clean Air Act of 1956 was a direct consequence, but while the air in London is now much healthier there are plenty of northern mining towns where smoke control has not even made a start. The incidence of bronchitis is strikingly correlated with the degree of atmospheric pollution, and bad air aggravates the harm caused by smoking cigarettes (see table).

What is less clear is the relative importance of different pollutants. Smoke particles and sulphur dioxide are the worst offenders in terms of atmospheric concentrations, but until the full effect of smokeless zones has been realized, nobody can establish how much illness the two pollutants may cause separately. Carbon monoxide and lead from motor exhausts, the survey finds, do not reach obviously poisonous concentrations even in the most crowded traffic, but there is some evidence that small concentrations of

INCIDENCE OF BRONCHITIS IN RELATION TO SMOKING AND AIR POLLUTION (DATA OF P. M. LAMBERT AND D. D. REID)

	Standardized morbidity ratio* (per cent)			
	Very low pollution	Low pollution	Moderate pollution	High pollution
Non-smokers	41	52	67	71
Smokers	121	131	159	209

* Based on 100 per cent for incidence of chronic bronchitic symptoms in Britain as a whole.

carbon monoxide can interfere with concentration and perception, so that a loss of efficiency may be hidden behind the lack of overt morbidity.

Naturally enough, the survey's chief recommendation is simply to get rid of smoke, an aim that can be achieved to a high degree by outlawing the domestic coal fire. Meanwhile research should be directed towards avoiding the damage from the gaseous pollutants, ideally by reducing the sulphur content of fuels, and towards discovering their more subtle interactions with vehicle exhausts and tobacco smoke.

BULGARIA

Homage to St Cyril

by our Soviet Correspondent

THE recent announcement that the Bulgarian government has awarded Academician M. Keldysh, president of the Soviet Academy of Sciences, the Order of Cyril and Methodius (1st Class) for his services to science, seems somewhat symbolic of the whole background of the Bulgarian Academy of Sciences, which is now celebrating its centenary. On the one hand, there is the long academic tradition, symbolized by the Order named after the ninth-century "Apostles of the Slavs", who evangelized Bulgaria and formulated the Cyrillic alphabet, and on the other, the strong ties of modern Bulgarian scholarship with Russian traditions.

For, although founded in émigré conditions (Bulgaria being then under Ottoman rule), without the royal or governmental patronage under which such academies are normally born, the Bulgarian Literary Society (as it was then known) early established close and continuous links with the scientific establishments of the then Russian empire, notably with the Imperial Academy of Sciences of St Petersburg (now the Academy of Sciences of the USSR). And, over the last twenty-five years, the Bulgarian Academy has been remodelled. In the words of its vice-president, Academician Vladimir Georgiev (in his centenary address), it became "an institution of a socialist type, with specialized institutes and laboratories, which greatly broadened its field of activity".

The Bulgarian Academy of Sciences, in fact, now comprises ten departments, some fifty research institutes, as well as a number of other specialized centres, a number of which have been endowed by the Soviet Union which, for example, built the atomic pile at the Institute of Physics. The publications of the academy number sixty-three original journals and serial publications and three abstract bulletins.

In spite of its close links with the academies of the Soviet Union and other Eastern European countries, the Bulgarian Academy of Sciences has established several distinctive fields of research. The Institute for Organic Chemistry has recently obtained some most interesting results on the structure of new alkaloids isolated from Bulgarian-grown plants. The Division of Metallurgical Science and the Technology of Metals is engaged on a vast R and D project on the development and application of new alloys, based on the metals already produced by the Bulgarian metallurgical industry and the mineral resources of Bulgaria. The considerable bias placed by the Geophysical Institute on research in seismology is not unconnected with the fact that Bulgaria lies in the Balkan seismic zone.

Yet, in spite of this bias towards national conditions and problems, the Bulgarian Academy of Sciences has progressed far beyond its original aim of "disseminating general knowledge among the Bulgarian people and showing them the path to prosperity". Recent achievements of international significance include the formulation of new algorithmic languages (notably ALGAMS), the development of the "ferrograph" device for measuring the rectangular hysteresis curves of ferrite cores, the development of apparatus for measuring electron paramagnetic resonance, a new and more sensitive method for the rapid registration of the mass numbers of gases and vapours *in vacuo*, investigation of the D-layer of the ionosphere, chemistry of monomers and high polymers, microminiaturization of electronics and integrated circuits and other topics of contemporary interest.

The centenary celebrations of the academy began in October 1969, and will continue through the academic year, concluding with an international psychological conference to be held in the Black Sea resort town of Varna in September.

WATER RESOURCES

More Reservoirs for the North

A BARRAGE across the Solway Firth for estuarine storage of water will not be an economic proposition in the foreseeable future, according to the Water Resources Board (*Sixth Annual Report of the Water Resources Board*, HMSO, 10*s*; *Water Resources in the North*, HMSO, £1 16*s*). Instead, water supplies for the north-east of England should be met adequately during the next thirty years by one or two additional inland reservoirs which, the board says, will be nearer the centres of demand, and will be more acceptable aesthetically than a construction in the Solway Firth.

To meet the demands for water in the rest of the north of England in the period 1981 to 2001, the board suggests that the choice lies between more inland reservoirs (four or five), and water storage in Morecambe Bay or the Dee Estuary, or both. But this choice, it says, must be made in 1971 or 1972, and it urges that there should be further investigations soon of inland sites suitable for reservoirs. Two or three such sites may be required as early as 1976 or 1977, but the board does not see its scheme for augmenting water resources in the north becoming fully operative until 1981 at the earliest. The final choice will, of course, depend to a large extent on the results of the Morecambe Bay and Dee Estuary studies. Both studies are past the half-way stage, and final reports are expected in 1971. Progress on the third barrage being considered by the board, that across the Wash in the east of England, is not as advanced, but the board hopes to receive shortly the consulting engineers' report on the desk study which has been under investigation since 1968.

While the board believes that estuarine barrages and more inland reservoirs are necessary to meet all the future demands for water in England and Wales, much more will depend, it says, on the proper management of water after it has been used. The board would therefore like to see the sewage authorities reduced in number and made more efficient, their work planned and coordinated on a national scale, and the board's functions extended to cover the disposal of water after use so that it could have control over all aspects of water management.

NEW UNIVERSITY

Campus in Tropical Australia

from a Correspondent

ONE of the events marking the bicentenary of Captain Cook's discovery of eastern Australia is the opening of a university which bears his name. The bill setting up the James Cook University of North Queensland received royal assent during the Queen's visit on April 20. The new university was previously the University College of Townsville, part of the University of Queensland, Brisbane, promoted to full status after nine years. Situated on the Coral Sea coast near the Great Barrier Reef, the university at Townsville is the first in tropical Australia. The vice-chancellor is Dr K. J. C. Black, who was appointed warden of the college in 1963.

All facilities are being transferred from the present two campuses to a 650 acre parkland site in a natural amphitheatre bounded by the Mount Stuart Range. Most of the students, who number more than 1,200, are accommodated in residential colleges in the new setting. This year there are twenty-five per cent more matriculants than last year, a trend which is expected to continue.

This year ordinary and honours bachelors and higher degree courses will be offered in faculties of arts, commerce and economics, education, engineering and science. There are also provisions for candidates for other degrees at the University of Queensland, including medicine, dentistry, agriculture, veterinary science and law, to spend their first year at Townsville. A graduate school of tropical veterinary science was founded last year.

The situation of Townsville on the Coral Sea coast near the Great Barrier Reef is ideal for marine scientists. There will be opportunity for collaboration with the Australian Institute of Marine Science, which is to be set up at Townsville. The university is to have its own department of marine sciences, and has been allocated funds for a research vessel.

In the department of chemistry, where particular emphasis is placed on carbohydrates, research interests include the structure and metabolism of polysaccharides of tropical flora, and aspects of ruminant metabolism, as well as more fundamental chemical topics. Research interests in the department of physics are principally in radiophysics, wave propagation and low energy nuclear physics. The department is also responsible for the Tropical Research Unit in Atmosphere and Meteorological Physics.

In the department of engineering and geology, courses and research are oriented particularly towards industrial and mining developments in Queensland and other parts of Australia. Close liaison is encouraged with private industry and government agencies, which supply scientists who make specialist contributions to the teaching of the university.

As its graduate studies extend in scope, the James Cook University will increase its intake of students from South-East Asian, African and other overseas countries, especially in subjects of vital importance to tropical development, for example, veterinary science and engineering. It is one of the aims of this university to make its facilities available to other countries with tropical needs, as well as serving North Queensland and the rest of tropical Australia.

Parliament in Britain

Military Hovercraft

THE government has no intention of abandoning any projects concerned with military hovercraft development. This assurance was given by Lord Delacourt-Smith, Minister of State, Ministry of Technology, in reply to a question from the Earl of Kinnoull. He said that the BH7 model, which is now undergoing trials, has already been bought by the Ministry of Technology for evaluation by the Navy and that five models of the SRN 6, four of the SRN 5 and one of the SRN 3 are in service. The government is also discussing the possibility of assistance for further development both of existing and of planned craft with the British Hovercraft Corporation. (Oral answers, Lords, April 14.)

CS Gas

ALTHOUGH Mr Eric Moonman said that the United States produced 1,207,000 lb of CS gas in 1967, 4,251,000 lb in 1968, and 6,063,000 lb in 1969, under licence to the British government, he was told by Mr Ivor Richard that no money has been received arising from the licensing arrangements. (Written answers, April 16.)

Power Stations

MR ALAN WILLIAMS, joint parliamentary secretary, Ministry of Technology, said that on January 1 this year, the Central Electricity Generating Board had 46,035 MW total generating capacity. This consisted of 35,957 MW coal fired, 4,766 MW oil fired, and 3,138 MW nuclear, and the rest was made up from coal-gas fired stations and other sources. (Reply to a question from Mr Eric Ogden, written answers, April 16.)

Aerospace Industry

THE British aerospace industry was the subject of a wide-ranging debate in the House of Lords last week. Discussion touched upon almost every aspect of the industry, and was liberally sprinkled with pleas for Britain to become more involved in space research. The Earl of Bessborough, who opened the debate, said, for example, that no country which wishes to remain in the forefront of advanced technology can fail to be involved in space, and if the British government can go in with the United States in the development of the space shuttle, then it ought to do so. But that viewpoint did not entirely carry the day. In characteristic style, Lord Ritchie-Calder declared his opposition to manned spaceflight. He said that he has always deplored the Apollo mission for its waste of human ingenuity.

As far as the British aerospace industry is concerned, Lord Delacourt-Smith said that the size of the industry must reflect the amount of work which it manages to obtain, and that it is not the business of the government to keep it at any particular level. He also said that even though the future of the industry may seem to lie in international cooperation—especially with European countries—it is not government policy to pursue this course willy-nilly and rule out national projects automatically. The Minister of State concluded by saying that although the government may play a major part in the British aerospace industry, it is essentially for the industry to carry out its own long-term planning in the light of its own commercial judgment. (Debate, Lords, April 15.)

NEW WORLD

Short Commons for NSF (Part 2)

THE opening of the Senate's inquiry into the budget of the National Science Foundation on April 16 served principally to underline the seriousness of the foundation's plight, already apparent from its application for funds to the House of Representatives some weeks ago (see *Nature*, **225**, 785; 1970). The foundation now seems to be reckoning that it would take $50 million to support the research projects likely to be abandoned by the Department of Defense and more still to make up for the reductions of expenditure by other mission agencies of the US Government. According to Dr W. D. McElroy, director of the National Science Foundation, however, the $10 million in the foundation's budget originally set aside for abandoned projects will have also to be spent on the increasing demand for research money from young investigators.

If, however, the prospect ahead is bleak, the National Science Foundation seems to have found for itself a new champion in Senator Edward Kennedy, the chairman of the Special Subcommittee on the National Science Foundation set up by the Labor and Public Welfare Committee of the US Senate. For one thing, Senator Kennedy has already introduced into the Senate a bill that would increase the National Science Foundation's budget in the coming year by $50 million, although it is too soon to know how effective a rallying point that will be. He is also seeking to dramatize the foundation's plight by inviting to a public inquiry on April 23 the four former Scientific Advisers to Presidents of the United States—Dr James T. Killian, Dr George Kistiakowsky, Dr Jerome Wiesner and Dr Donald Hornig. According to Senator Kennedy, the intention is that the Scientific Advisers should "appraise the current needs of the NSF and the scientific community", and it is also expected that Dr L. DuBridge, the current holder of the office, will be represented at the same time. Whether this public demonstration will melt the heart of Congress only time will tell, but it may well suggest that Senator Kennedy will later this year inherit the reputation of Representative Emilio Q. Daddario as the chief defender of the NSF in Congress when, in November this year, Mr Daddario seeks election as Governor of Connecticut.

Introducing the inquiry last week, Senator Kennedy said that "science and scientists are facing both unprecedented criticism and unprecedented opportunity", with some critics saying that too much is being spent on defence and too little on the environment. But in his view, "our scientific community may soon be better able to serve our domestic needs than it has been for a generation", chiefly because of what seems to be willingness to "reorder priorities". In spite of the increase in the foundation's budget for 1971, Senator Kennedy said that "the Administration's authorization does not adequately take into account the overall research picture".

Dr Philip Handler, speaking as chairman of the National Science Board, had a gloomy tale to tell. He said that the National Science Foundation has not fulfilled the promise of the chief agency for the support of science in spite of its successes in the fields in which it has been able to operate. He complained that federal support for scientific research began to taper off in 1968 and has been virtually stagnant since. It was all very well to ask that science should be more concerned with projects bearing on social problems, and the Mansfield amendment (not necessarily to be repeated in 1971) was a sign of this, but it was wrong to "warp scientific endeavour by concentrating too much on immediate problems". He pointed to the way in which the National Institutes of Health were now reducing expenditure on organic chemistry, simply because of the narrower view now held of what constitutes "health related research", but thought it ironical that this kind of research "is the only source of new ideas for an industry worth $40,000 million a year". Given that there is no reason to think that science in the future will be less productive than in the past, he pleaded for an agency with the broadest possible licence for the support of scientific research. He said that he had been "deeply troubled" at the meeting last week of the Federation of American Societies for Experimental Biology in Atlantic City by the conflict between the eagerness of young scientists to help with social problems and their feeling that "if the Federal Government has lost interest, perhaps they have made a bad choice of a career".

Dr McElroy said that it is too soon to assess the full effect of the Mansfield amendment, but that the good projects left without funds are likely to be worth between $50 and $60 million a year. He said that the foundation had been surprised by the comparatively rapid growth of new applications from young investigators, up by 17 per cent at the beginning of April, and he explained that these applications would also be a charge on the foundation's spare cash. Within its planned budget, however, the foundation is going to be quite generous to the social sciences: institutional support will increase from $0·5 million in the current year to $4·5 million next year. The disparity between the foundation's ambition and what it has to spend is perhaps most clearly illustrated by Dr McElroy's guess, in reply to prodding from the chairman of the subcommittee, that it would be easy to spend $800 million, more than half as much again, in 1972.

At the inquiry last week, there was a good deal of anxiety about the way in which the foundation has been asked to strike out from its budget the support of graduate students under its traineeship programme; although plans for this September will not be affected, Dr McElroy said, "I understand that the Administration is looking into the possibility of financing graduate students by means of loans". There is some optimism about the prospect of attracting laboratories such as Oak Ridge, Brookhaven and the Argonne Laboratory into some of the foundation's plans for multi-disciplinary research. Everybody's head was shaken in sorrow at the curtailment of the foundation's college improvement programme—in the current year, the foundation has been able to spend only $4·4 million on 575 proposals when it calculates that something like $10 million worth of valuable projects were included in the 1,600 proposals.

More Delay at Arecibo

One of the disappointments of Dr McElroy's statement to the Kennedy subcommittee was the news that the project to resurface the radio telescope at Arecibo in Puerto Rico has been postponed pending an engineering design study of the problems involved in mounting an exceedingly thin skin of perforated aluminium on the wire framework now being used. The original proposal was for an aluminium skin 0·008 inch thick perforated by square holes an eighth of an inch across to let wind and water through. The cost of the modifications, at the top of the list of projects suggested two years ago by the committee under Professor R. H. Dicke, was $3·8 million. By all accounts, the National Science Foundation was dissuaded a year ago from applying for the money. Dr McElroy said last week that a study of the proposal has now "raised a number of questions concerning problems relating to the installation of the proposed surface".

The feasibility of the project now depends on engineering design studies, and a new estimate of costs will be worked out on that basis. Dr McElroy said that he will go back to the appropriate Congressional committee with the new estimate as soon as this is available.

Dr Robert Fleischer, head of the astronomy section at the National Science Foundation, explained that the inadequacy of the original estimate of cost had come to light during a detailed examination of the proposal. He said that it now looks as if the original estimate might be low and that the foundation was anxious not to seem as if it had gone to Congress with an unrealistically low estimate in the hope of securing a degree of commitment that would not otherwise have been forthcoming. There is no doubt that the engineering problems are considerable. The intention is to resurface the dish, which is 1,000 feet across, so that it can operate at a wavelength of 6 cm, which means that the surface has to be geometrically accurate to within about 3 mm. It now looks as if a heavier surface than that originally planned will be necessary. One of the difficult points that will arise towards the end of the proposed engineering study, possibly six months from now, is that the cost of resurfacing Arecibo may be so great that a reordering of radio astronomers' priorities for new instruments will seem appropriate.

The second proposal in Professor Dicke's list, that for a 400 foot steerable dish enclosed in a radome and operated by a consortium of universities in the north-east, has moved a little forward, or at least sideways. Apparently with the tacit consent of the National Science Foundation, the natural sponsor, the Smithsonian Astrophysical Observatory, one of the consortium of would-be builders, is applying separately to Congress for funds to carry out a thorough design of the telescope. Although success is unlikely, this development does illustrate the despair which radio astronomers share.

TECHNOLOGY

Mr Wedgwood Benn Swings By

Mr Anthony Wedgwood Benn, who began his week in Washington on April 15 with a combined cocktail party and lantern slide lecture, left for Los Angeles after raising an astonishing number of questions with departments of the US Government. Little on the agenda has turned itself into formal agreements, and Mr Benn was careful to explain that that had not been his intention. On the question of whether the United Kingdom, with or without its European partners in ELDO, should collaborate with the United States in future space projects such as the space shuttle that NASA wishes to build, Mr Benn said, for example, that he would want to discuss several possibilities with the other members of the "lunch club" of European ministers inclined to take some interest. Mr Benn seems to think of Europe more as a customer of the American space programme than as a participant in it. No doubt the next European Space Conference in Brussels in July will help to clarify the position.

Mr Benn seems to have raised some interesting issues in his talks with the Department of State, chiefly on matters such as international technological collaboration on questions such as standardization. He has clearly been at pains to emphasize the potential importance to Britain of the various schemes for technical collaboration now being fostered by the Aigrain committee within the EEC, and of the possibility of British membership of the community. One of his views is that the time has come for governments such as the British Government to "open diplomatic relations with the international companies", and he said that he and American counterparts had agreed to exchange experiences. The environment seems to have featured in Mr Benn's talks both with Dr L. DuBridge and Mr Russell Train, the chairman of the Environmental Council. Although Mr Benn says that "my heart is in the environmental business", a part of his objective seems to have been to convince American officials that there must be coordinated international progress in the development of standards if some of the potentially awkward consequences of the improvement of the environment are to be avoided. One illustration of the difficulty of which British motor-car manufacturers are still vividly aware is the way in which the rapid introduction of stringent safety standards for American automobiles three years ago cut into British exports of some models. Last week, Mr Benn pointed out that the United States could not "ban the internal combustion engine by Thursday week" without sending all kinds of economic ripples about the world.

Among the other subjects on this crowded agenda was the Harrier aircraft, now being evaluated by the US Air Force, and the European consortium's plan for the development of the gas centrifuge, which Mr Benn talked over with the Atomic Energy Commission. Transportation seems to have played an important part in his discussions, both where the supersonic transport is concerned and with matters such as fast ground transport and automobile engines, where it has apparently been agreed that the two governments will keep in touch with each other.

Indeed, the most difficult meeting that Mr Benn expected to have in Washington during his current visit was with Mr John Volpe, the Secretary for Transportation. The objective was to obtain convincing reassurances that the United States was not going to ban supersonic overflights to the disadvantage of Concorde and then relax the rules later when American supersonic transport comes along. The Concorde is considered to have a comfortable five year lead over the American project at present.

At least Mr Volpe's official statement last week that a ban on supersonic overflights by civil aircraft is in view brought some clarification. In very carefully chosen language Mr Volpe gave notice of a proposed ruling which would ban all supersonic flights over the United States where it can be proved that the sonic boom will reach the ground. Exemption will be given to operators who can demonstrate that no sonic boom is generated by a supersonic flight. Perhaps this language need not be taken too seriously. It seems that Mr Volpe was adopting a procedure for alerting interested parties—such as Mr Benn—to future regulations before they finally crystallize. Comment on the ruling is invited up to June 15, and Mr Benn seems to have reacted swiftly. The day after the announcement he offered to provide all the data of Concorde test flights over land to allay American fears on Concorde's "noise pollution" characteristics. Ironically, the Ministry of Technology spends more on research into noise than on any other form of pollution. Of course, this is nothing like as much as it spends on Concorde.

New GRAS List

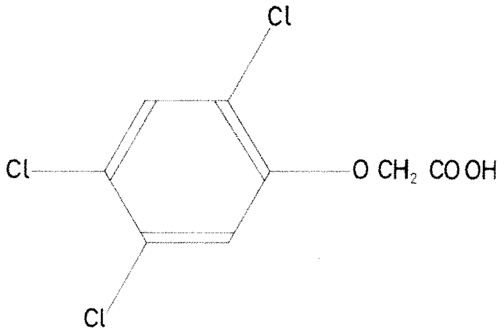
The day after the appearance of the latest Nader report, but not on that account alone, the Food and Drug Administration asked that food manufacturers in the United States using food additives licensed in the palmy days before 1958 should reapply to have these included in the list of materials generally recognized as safe (GRAS). An official of the FDA explained that when the present formal procedures for including materials on the GRAS list were introduced in 1958, a large number of compounds used with food additives had been approved on the basis of advice of variable quality and in comparatively informal ways. What has happened now is that food manufacturers have been asked to reapply for the inclusion in the GRAS list of food additives originally approved before 1958. The FDA has undertaken to give some kind of an answer within 30 days. By all accounts, it does not know how many compounds will be affected—it may be anything between 1,000 and 10,000. Much will depend on the extent to which previous permissions are subsumed in later more formal approvals.

Another Herbicide on the Blacklist

Herbicidal chickens from Vietnam came home almost literally to roost last week when Dr M. Jacqueline Verrett of the Food and Drug Administration showed off to the chairman of a congressional committee two trays of deformed chicks born of eggs dosed with the controversial herbicide 2,4,5-T. She followed the surgeon-general of the United States, Dr Jesse L. Steinfield, who told the Subcommittee on Energy, Natural Resources and the Environment of the Senate Committee on Commerce that the secretaries of Agriculture, the Interior and Health, Education and Welfare had decided to restrict the use of 2,4,5-T in circumstances when foodstuffs for human consumption might be contaminated. With his tongue ostentatiously in his cheek, Dr Julius E. Johnson, director of research at the Dow Chemical Company, told the subcommittee that he did not think this decision was warranted if the issue was simply a matter of public health, although "in the climate of today, I think it was a wise decision". The inquiry did, however, throw light on several apparent conflicts in previous reports about the hazards of 2,4,5-T by showing that many of the mutagenic and teratogenic effects attributed to 2,4,5-T are really caused by a much more toxic impurity, 2,3,7,8-tetrachlorodibenzo-*p*-dioxin. This material and its congeners are likely to attract a good deal of attention in the months ahead.

Dr Steinfield said on April 15 that the evidence on which the three departments had decided to ban 2,4,5-T had become available only at the previous weekend, which goes some way to explain why officials of the United States Department of Agriculture had taken a more complacent line about the herbicide in their evidence to the subcommittee only a week before. The immediate effect of the decision is to suspend current permissions (or registrations) for the use of liquid preparations of 2,4,5-T domestically and on lakes, ponds and ditches. At the same time, the United States Government has revoked permissions to use non-liquid preparations of the herbicide domestically and on crops of all kinds. Preparations in the first category will remain in limbo unless further research allows the restriction to be relaxed. It will still be possible legally to use 2,4,5-T for the control of weeds on pasture land, footpaths and forest ground, which means that people who are sensitive to poison ivy and poison oak, two of the natural scourges of North America, can still hope for some relief by the use of the weed-killer which is most effective against them.

Dr Steinfield's announcement is a victory, even if somewhat muted, for groups of scientists who have campaigned against 2,4,5-T on two separate counts during the past six years. The herbicide has been widely used in Vietnam as a defoliant, and the American Academy for the Advancement of Science has done stalwart if somewhat intermittent work to draw attention to the long-term ecological hazards of the practice. (A committee under Professor M. Mendron of MIT plans to have a report on the subject by the end of 1970.) More recently, there has been concern about the potential teratogenic effect of 2,4,5-T, especially in an article in the *New Yorker* by Mr Thomas Whiteside last December. This is the point which has now been conceded by the United States Government, although Dr Steinfield also announced last week that the Department of Defense had also asked those responsible for defoliation in Vietnam to pay



2,4,5-Trichlorophenoxyacetic acid

heed to the findings which have now come to light.

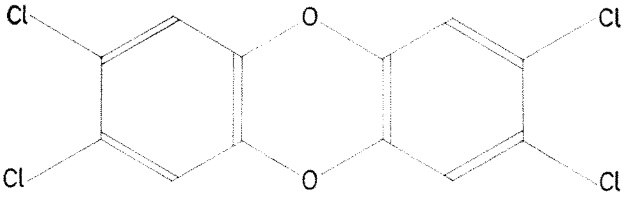
The inquiry last week showed that impurities in 2,4,5-T must play an important part in any discussion of its toxicity, and the way in which this has been worked out promises to become a classic in the history of chemical detective work. The Dow Company and Dr Verrett seem to take much of the credit. The herbicide 2,4,5-T (2,4,5-trichlorophenoxyacetic acid) is a synthetic auxin which kills weeds systemically. Like the similar material 2,4-dichlorophenoxyacetic acid (2,4-D) it has featured in the rapid growth of herbicide applications in the United States in the past decade or so. Although there have been reports, necessarily hard to confirm, that the use of these materials in Vietnam has increased the incidence of congenital malformations among people, the first objective evidence of a teratogenic effect of commercially available 2,4,5-T seems to have been provided by a lengthy search for teratogenic effects in pesticides (forty-eight materials altogether) carried out between 1965 and 1968 by the Bionetics Research Laboratories, under contract with the National Cancer Institute. More than a year after the Bionetics studies were completed, on October 29, 1969, Dr L. DuBridge in his capacity as executive officer of the Environmental Quality Council announced that the use of 2,4,5-T by departments of the federal government would be restricted, and that the use of the material in agriculture would be curtailed unless safe limits could be established by the beginning of 1970. One of the muddling features of this case to emerge at the inquiry last week was that the influential Mrak Commission on Pesticides (which counted herbicides in its field of interest) was not told of the results of the Bionetics study until Dr DuBridge's announcement. Another is that the Department of Agriculture seemed at first studiously to ignore what Dr DuBridge had to say, which is why last week's developments were something of a vindication of his reputation.

According to Dr Julius Johnson of the Dow Chemical Company, one of several manufacturers of 2,4,5-T, his company responded to the announcement last October by making a search for impurities in the product. The herbicide is manufactured from 1,2,4,5-tetrachlorobenzene by hydrolysis (to form the sodium salt of 2,4,5-trichlorophenol) which is then treated with the sodium salt of monochloroacetic acid. Dr Johnson said that "since 1950 we have been keenly aware" that highly toxic compounds are formed from 2,4,5-trichlorophenol at high temperatures, and in 1965 the chief offender was identified as 2,3,7,8-tetrachlorodibenzo-*p*-dioxin. This happens to be not merely one of the agents responsible for sporadic outbreaks of an occupational disease most recognizable as a severe acne among workers at chemical plants, but also as one of the contaminants in chicken food fortified with fatty acids now known to be responsible for the "chicken oedema disease" which has plagued poultry farmers for close on two decades. According to Dr Johnson, the Dow plant was modified in 1965 so that the amounts of dioxin in 2,4,5-T were less than 0·5 parts per million. The inference is that materials in circulation before 1965 included larger proportions of the dioxin, and the sample used in the Bionetics study (manufactured by the Diamond Alkali Company) has now been shown by gas–liquid chromatography to contain 27 ± 8 parts per million of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin. Although information about the manufacturing hazards seems to have been shared within the chemical industry, Dr Johnson's account last week suggests that the possibility that dioxin in herbicide could cause teratogenic effects in mammals was taken seriously only in late October last year, when Dr DuBridge made his announcement and the results of the Bionetics study were communicated to the Mrak Commission, of which Dr Johnson was a member.

In the past six months, studies of 2,4,5-T and its chief dioxin contaminant have been carried out by the Dow Company, the National Institute of Environmental Health Sciences and the Food and Drug Administration, chiefly in the search for teratological effects. The surgeon-general said last week that the decision to restrict the use of 2,4,5-T had been based on the finding at the National Institute for Environmental Health Sciences that "nearly pure 2,4,5-T was reported to cause birth defects when injected at high doses into experimental pregnant mice but not in rats". According to Professor Samuel S. Epstein of the Children's Cancer Research Foundation, Boston, the chairman of the Mrak Commission's panel on teratology, who also appeared at the inquiry last week, these studies (in which pregnant mice were dosed with 2,4,5-T) indicated cleft palates "at dose levels of 150 mg/kg and scattered abnormalities at 100 mg/kg; the cleft palate incidence in control mice was essentially zero".

The Bionetics study in which the teratological effects of impure 2,4,5-T were first recognized was more alarming—in one series of experiments, for example, the oral administration of 113 mg per kg to AK mice on days 6 to 15 of pregnancy produced 49 per cent of deformed foetuses, among which cleft palate was conspicuous. The same study, with small numbers of animals, showed that Sprague–Dawley rats are also sensitive. These results are no longer a sure guide to the behaviour of 2,4,5-T because of the contamination of the sample used with dioxin.

The studies carried out by the Food and Drug Administration and described last week by Dr Verrett



2,3,7,8-Tetrachlorodibenzo-*p*-dioxin

have been made with recrystallized 2,4,5-T and with samples of 2,3,6,7-tetrachlorodibenzo-*p*-dioxin. The technique of injecting these materials into fertile hen's eggs, which has been used in screening materials suspected of causing chicken oedema disease, produced the collection of malformed chicks which Dr Verrett exhibited last week and provided the committee chairman, Senator Phillip Hart, with a splendid opportunity to hold normal and abnormal chicks in front of the television cameras, but both the surgeon-general and Dr Johnson of Dow argued that chick embryo studies are not reliable guides to the potential teratogenic effects of chemicals in other species. Dr Verrett's purpose seems to have been to compare the potency of the various materials used, and from her statement it would seem that 50 micrograms of the new 2,4,5-T manufactured by Dow produces chicken oedema symptoms and structural abnormalities with the same frequency as 6·25 micrograms of the sample used in the Bionetics study. Recrystallized herbicide also produced abnormalities in chicken embryos, but only at doses five times as great. On this scale, there seems no doubt of the greater potency of the tetrachlorodioxin—one nanogram of this material seems to have produced disturbed embryos with noticeable frequency.

Dr Verrett also described last week studies with pregnant hamsters. Manufactured 2,4,5-T with an estimated 0·5 p.p.m. of tetrachlorodioxin killed 80 per cent of the foetuses at a dose of 100 mg/kg, but the three-times recrystallized sample produced 55 per cent of foetal deaths at the same dose and three out of the thirty-eight pups born alive turned out to be malformed. According to Dr Verrett, with a preparation that was still more carefully purified, early foetal deaths worked out at 70 per cent, but there were no "gross terata" at 100 mg/kg. The dioxin turns out to be roughly 1,000 times more effective—9·1 micrograms per kilogram produced 98 per cent of foetal deaths.

Dr Verrett's conclusion was that both 2,4,5-T and 2,4-D taken from production runs are teratogenic, and that even the purified sample, 2,4,5-T, is suspect, "making it impossible at this time to exonerate it of teratogenic and other adverse effects on the embryos that may have some health significance".

One of the disconcerting features of the results made public last week is that the three independent groups of investigators have used different test animals, which means that direct comparisons are complicated. The investigations carried out by the Dow Company have been with Sprague-Dawley rats, apparently by agreement with the Food and Drug Administration. 2,4,5-T from the Dow production line, containing an estimated 0·5 p.p.m. of tetrachlorodioxin, seems to have produced no embryo losses at doses up to 24 mg/kg, at which level, however, 29 out of 103 foetuses were deficient in sternebral ossification (compared with four foetuses in the control group of the same size). A separate Dow study has shown that the tetrachlorodioxin contaminant will stimulate the resorption of foetuses when fed to rats between the sixth and fifteenth days of pregnancy at 2 micrograms a day or more, that gastro-intestinal haemorrhage is found between 0·125 micrograms a day and 8·0 micrograms a day, and that there is a reduction of foetal weight within this range. Professor Epstein pointed out last week, however, that these results raise new issues, for cystic kidneys were rare among the congenital abnormalities produced in the most recent Dow studies, but common—and presumably the results of dioxin contaminant—in the Bionetics study. "This discrepancy may reflect synergistic interaction between dioxin and 2,4,5-T."

A somewhat breathless account of the latest Dow experiments by Dr Johnson suggests, among other things, that this may be so. To begin with, it was established that a dose of 100 mg/kg/day of 2,4,5-T would kill 75 per cent of pregnant rats, but that the animals could tolerate half that amount with considerable physiological stress, including the resorption of foetuses. Results which, last week, "were only available yesterday" show that the addition of microgram quantities of the tetrachlorodioxin to this dose produces significant teratological effects only at the level of 6 micrograms/kg/day (in experiments in which pregnant rats were fed the materials between the sixth to the fifteenth days of pregnancy). Eight per cent of 155 rats born after such a regimen showed signs of gastro-intestinal haemorrhage. With the addition of 0·5 micrograms/kg/day and twice that amount respectively to the base level of 50 mg/kg/day of 2,4,5-T, four and five out of fifteen newborn rats were found to have cleft palates.

This is the point at which Dr Johnson entered his most vigorous defence of 2,4,5-T. He started from the surveys of the Food and Drug Administration which have sought evidence of the herbicide in actual samples of food, and which have revealed only trace quantities —less than 0·1 part per million—in 25 out of 5,300 food samples, with one sample containing 0·19 p.p.m. and another 0·29 p.p.m. On the assumption that all food contains 0·2 p.p.m. of 2,4,5-T and that this is contaminated with 1 p.p.m. of tetrachlorodioxin, a person would accumulate a dose of 11 micrograms in 100 years. This, according to Dr Johnson, is a "600-fold safety factor compared with what we estimate to be the embryo-toxic effects in rats", with the proviso that the whole amount must be delivered during the appropriate stages of pregnancy. This calculation was the basis for the air of puzzled resignation with which Dr Johnson greeted the restriction on the use of 2,4,5-T—but Dow reserves the right to appeal against the new regulations when these are published.

By the end of the inquiry, however, the prospect of contamination by other kinds of chemicals had captured the attention of the subcommittee. Dr Verrett was the first to point out that no account had been taken of the still unknown teratological effects of the large numbers of isomers of tetrachlorodibenzo-*p*-dioxin which might also be present in manufactured herbicide. She went on to chill the subcommittee with the news that the way in which these materials can be produced by the pyrolysis of substituted chlorophenols means that there are potential hazards in the burning of great variety of materials to which various chlorophenols are added during manufacture—paper, leather and the like. Professor Epstein gave a more deliberate recitation of the same case—he argued forcefully for more information about the formation of dioxins from all kinds of chlorophenols and more information about the teratogenicity of the dioxins. "Available data . . . indicate an urgent need for restriction of human exposure to dioxins. Similar restrictions should extend to polychlorophenols, polychlorophenolic containing formulations and their combustion products."

NEWS AND VIEWS

Squeezing some More from the Earth

It might have been thought that once seismology had presented a clear picture of the elastic properties of the Earth it could disappear gracefully from the scene. The trouble, or to the insider the virtue, is that the more carefully the Earth is studied the less it is possible to fit its elastic properties into any simple spherically symmetric model. The structural difference between the upper mantle under continents and under oceans is believed to extend to a depth of at least 600 km. Substantial slices of the mantle in which deep earthquakes occur (for example, round the Pacific) are known to be out of thermal equilibrium with their surroundings. The techniques for determining earthquake mechanisms have been improved beyond all recognition in the past three or four years. And commanding increasing support is the earthquake prediction programme, which is quietly being renamed the earthquake control programme. So the future still holds lots of prizes for the seismologist.

New problems are very often best attacked with new tools and in the past two years there has been a spate of instrumental developments. Coverage of the world with short period (1 s) instruments is now reasonably good. These instruments are of particular use in location of events, and work with magnifications up to a million. There are several "holes" in global coverage—the Pacific Ocean, the Arctic, Africa—but stations on Pacific Islands, in Northern Canada and Siberia and in Kenya, Ethiopia, Egypt and South Africa help to plug the gaps. The longer period instruments (10 s up to thousands of seconds) are less thick on the ground and are particularly inadequate for periods greater than 40 s. Such seismometers are of use in studies of earthquake mechanism, distribution of strain patterns before and after earthquakes and study of the deeper structure of the Earth by long-period surface waves and free vibrations of the Earth. It goes without saying that they are of considerable value in nuclear test detection. The number of such seismometers in use, however, is now increasing rapidly. Particularly noteworthy are the novel designs that are being used.

At least four new types of laser seismometer have been designed in the past two or three years. These are strain measuring devices which work as interferometers with automatic fringe detection. Strains as small as 1 in 10″ may be measured and laser seismometers with a broadband response are extremely versatile seismometers. Because the optical paths are usually *in vacuo*, environmental control need not be stringent. Although two or three work in disused railway tunnels, one (800 m long) sits on the ground basking in the Californian sunshine.

Last year some impressive new results were demonstrated by Molnar *et al.* (*Nature*, **224**, 1268; 1969) using careful environmental control of a conventional long period seismometer and improved amplification devices. Undoubtedly these new Lamont seismometers will open up fields of research in a part of the spectrum so far very inadequately treated.

In this issue (page 343), Block *et al.* describe some of the results recently obtained with the new accelerometer developed at Scripps during the past three or four years. This instrument is interesting in that it was designed by physicists to see how good an accelerometer could be made, rather than by geophysicists with particular problems in mind. The result is quite remarkable. Block *et al.* report very clear excitation of the free oscillations of the Earth from a magnitude 6·5 earthquake. There are generally at least twenty earthquakes of this magnitude or greater every year. To put this achievement in perspective we may note that free oscillation observations had only previously been possible from earthquakes with magnitudes greater than 7·7, and that only two earthquakes (Chile, 1960; Alaska, 1964) have received widespread attention. It is reported that, since the New Hebrides earthquake, several other earthquakes have allowed the measurement of free oscillations.

It seems that a new era of instrumental development and increased seismological knowledge is opening. The subject is clearly going to be as lively in the next decade as it was in the last.

COMETS

Another Hydrogen Cloud

by our Astronomy Correspondent

A second example of a cloud of hydrogen surrounding the head of a comet was reported last week by NASA. Observations from one of the Orbiting Geophysical Observatories show that comet Bennett which first appeared over Australia in January is immersed in a cloud of hydrogen about eight million miles across—ten times the diameter of the Sun.

This follows the news of a hydrogen cloud surrounding the comet Tago-Sato-Kosaka, announced by NASA earlier this year from data obtained with the Orbiting Astronomical Observatory, OAO 2 (see *Nature*, **225**, 413; 1970). The size of the cloud around Tago-Sato-Kosaka was said to be comparable with the size of the Sun.

Although the hydrogen clouds are unexpected, they are fairly simple to account for on the current model for cometary nuclei. As the comet approaches the Sun some of the gases which are contained in the mass of mineral particles and frozen gases which make up the nucleus would be expected to boil off. The problem is that the coma of gas surrounding the nucleus, which is recognized to be the result of this process, is tiny by comparison with the hydrogen clouds now observed.

The reason why the hydrogen clouds have not been observed before is that the ultraviolet radiation which they emit is at too short a wavelength to penetrate the atmosphere. Both clouds were discovered with detectors sensitive to the Lyman α line of hydrogen at 1216 Å. Following the discovery of the cloud around Tago-Sato-Kosaka, the Lyman α detector on OGO 5 was pointed at comet Bennett on April 1 and 2 for two scans across the cloud. The detector in OGO 5 was developed by Professor J. E. Blamont's team at the University of Paris, and a preliminary map of the hydrogen distribution shows the cloud slightly elongated away from the Sun, as might be expected.

Comet Bennett was at its maximum brightness of 1·5 stellar magnitudes between March 21 and 25. According to NASA, there are also plans to observe the hydrogen cloud from OAO 2 and possibly using Mariners 6 and 7—the spacecraft equipped with ultraviolet detectors that last summer made close approaches to Mars.

LIGHT

Polarized Beams Divided

CIRCULARLY polarized light will be reflected in a different way from a surface depending on whether the polarization is to the left or to the right, according to C. Imbert of the Orsay Institute of Physics (*Phys. Lett.*, **31**, 337; 1970). In an experiment involving two different shapes of prism, he has shown that when two beams of light circularly polarized in opposite senses are totally reflected from a surface a separation appears between the beams which, when amplified, can be directly observed.

Although this strange result has been predicted from solutions of Maxwell's equations of electromagnetism, this seems to be the first time that the effect—known as the photon's translational inertial spin effect—has been confirmed experimentally. What it means, effectively, is that the momentum and velocity of photons in a circularly polarized beam of light are not collinear, or at least not collinear in the conditions of this experiment.

A beam of laser light was split into two circularly polarized parts by inserting a quarter wave plate followed by a half wave plate covering half the beam area. The light then fell on to a prism with one totally reflecting surface, and the expected divergence between the beams was multiplied by a series of internal reflexions inside the prism. Two types of prism were used, one giving twenty reflexions and the other thirty.

A rectilinear object with a clear edge was interposed between the half wave plate and the prism. The separation between the beams was then visible on the final image as a shift between the two halves of the edge. Imbert found that the size of this shift agreed with predictions to within the fairly generous experimental error. He points out that for circularly polarized light the momentum and velocity of a beam are not necessarily non-collinear, but that for total reflexion from a surface this separation seems now to be established.

THIN FILMS

On the Surface

from a Correspondent

THE newly formed Institute of Physics Thin Films and Surfaces Group held its first conference at the University of Reading from April 6 to 8. The theme was electronic properties of surfaces and thin films. Almost half of the contributions concerned aspects of amorphous thin films, which were introduced by Professor Sir Nevill Mott (University of Cambridge), who reviewed theories developed from a model of random depth potential wells. He pointed out that the plot of the logarithm of the observed conductivity against reciprocal temperature could be explained in terms of conduction in non-localized states at higher temperatures, by hopping between localized states at the bottom of the band for medium temperatures and by phonon assisted tunnelling by electrons at the Fermi level at low temperatures. Further experiments, for example, comparing thermo-power with conductivity and deliberately introducing acceptors by ion implantation, could provide more evidence about this model. In this context Drs J. G. Perkins and P. T. Stroud (Atomic Weapons Research Establishment, Aldermaston) showed that their technique for "knocking-on" atoms from a metal top electrode into silicon oxide films using 50–80 keV argon ions gives extremely reproducible results.

Dr R. M. Hill (Chelsea College of Science and Technology) showed how the conductivity and its temperature dependence could be explained by considering just one conduction mechanism, involving tunnelling and field emission from Poole–Frenkel defect centres, over the whole temperature range.

Professor A. K. Jonscher (Chelsea College of Science and Technology) presented an impressive collection of experimental data, obtained from amorphous SiO using photocurrent measurements, showing great reproducibility for various different contact metals and polarities of the applied voltage.

Clearly there are still theoretical problems, from the discrepancies between the various ideas presented, but at least it seems that the experimental results are consistent enough to apply theory.

Moving from amorphous to polycrystalline films, Professor J. C. Anderson (Imperial College, London) showed how the Fuchs–Sondheimer theory of surface scattering could be applied to semiconductors and extended to include the effect of surface band bending. He also showed how scattering at grain boundaries can have a large influence on the transport properties of polycrystalline films. Dr J. H. Fisher (Imperial College, London) showed how a similar theory could explain the Hall effect data from thin InSb films. For epitaxial semiconductors Dr M. R. Jordan (Plessey Co., Caswell) showed that PbSnTe films gave better than the best bulk results so far reported for mobility and that the films would be useful as infrared detectors in the 10 μm region.

When attention turned to semiconductor surfaces, Dr B. H. Blott (University of Southampton) reviewed theoretical and experimental work involving low energy electron diffraction and back scattering on the structure of surfaces. He pointed out that it is easier theoretically if the inelastically scattered electrons are used.

Dr V. Heine (University of Cambridge) reviewed some of the theoretical work on surface states which predicts the intrinsic states on both diamond and zincblende types of semiconductor. For an oxide coated surface the surface states could be caused by charges in the dielectric. Dr M. Pepper (Plessey Co., Caswell) showed that there is a correlation between the slow states and fast states for the Si–SiO_2 system. From theory Dr A. A. Cottey (University of East Anglia) predicted that there may be a size effect associated with a little known state of an electron at the band edge in a crystal.

Continuing on size effects, Dr R. J. Cruickshank (University of Aston) discussed results which showed that the galvanomagnetic properties of Bi were an oscillatory function of thickness. This was explained in terms of standing Bragg waves in the crystallites.

Professor H. Mayer (Clausthal) reported experiments using the photo-electric effect to excite surface and volume plasmons in alkali halide films. He pointed out that the use of thin films enabled the surface plasmon frequency to be measured. Dr R. H. Ritchie (Oak Ridge National Laboratory) also considered plasmons when he reported some novel ways for studying the surface structure using coupling between surface modes.

METEOROLOGY

No Clouds for Nimbus

THE most detailed mapping ever of the temperature of the atmosphere has just been sent back from a British experiment on the American Nimbus 4 satellite, Dr B. J. Mason, director-general of the Meteorological Office, told a meeting of the Royal Meteorological Society in London last week. In the six days since Nimbus 4 was launched on April 8 more than 30,000 temperature profiles were accumulated from infrared spectra of carbon dioxide in the atmosphere, providing valuable information for future long range weather forecasting. With the satellite sweeping out thirteen orbits of the Earth each day it is hoped to compile an accurate chart of the atmosphere up to an altitude of more than 50 km.

Encouraged by the results of the Nimbus programme, in which two satellites still remain to be launched, Mason believes that satellite experiments may revolutionize the study of medium scale air motions, which affect areas up to three or four hundred miles across. Large scale air movements across whole continents can usually be well simulated in numerical models, he explained, but motions on a smaller scale are poorly understood and have to be represented on a statistical basis. The physics of medium scale motions are still too unclear to know just how inherently predictable the atmosphere is.

A large tropical observing experiment is to be mounted in 1974 to study how heat is transferred from the tropics to other regions and to investigate the air–sea interaction. Mason hoped that Britain would participate in this research, and foresaw a further two or three similar experiments being set up before the end of the century.

The most significant advance in forecasting in the next ten years is likely to occur in five to seven day predictions. The demand for forecasts is growing by 20 per cent each year and the gas and electricity authorities are now asking for hourly temperatures predicted up to three days in advance. This is not yet possible, but it is hoped to introduce rainfall predictions for up to two days ahead on a 40 km grid across Europe as soon as a new computer is introduced in 1971.

Thirty day forecasts are improving all the time. Mason pointed out that there was only one total failure in Britain last year out of twenty-four predictions, compared with five for 1968. He saw this as the area of forecasting most likely to benefit from an improved understanding of the atmosphere during the next thirty years.

The best chance of improving long term forecasts lies in numerical models, Mason said. At present the limiting factor is the speed of computer calculations, but tardy dissemination of data is also a serious handicap. A chart which takes twenty seconds to produce on a computer can take up to twenty minutes to transmit elsewhere. Digital techniques are now being deployed in the United States to reduce this time to less than a minute, and for a station such as that at Bracknell producing 400 charts a day this is clearly an important bottleneck to loosen.

ANTARCTICA

Glacial History

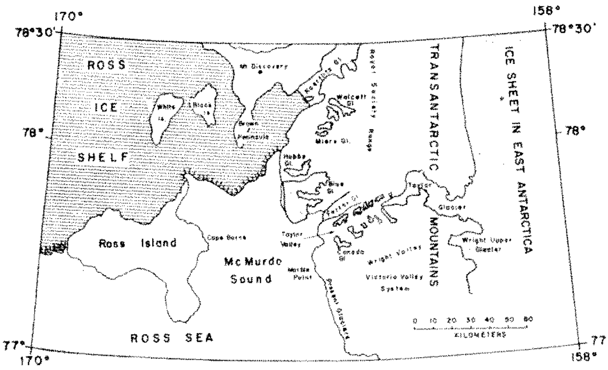
from our Geomagnetism Correspondent

THE most important questions to be asked about the Antarctic Ice Sheet are the obvious ones: What is its history ? When and why did it form ? Has it existed continuously since its origin or has it ever partly or completely disappeared ? Has it undergone changes in area and volume, and if so, were these changes contemporaneous with worldwide glaciations ? And from the past, what can we infer of the future ? Will the future behaviour of the ice sheet involve large surges, widespread melting, stability, or continuation of the present growth ?

These are some of the questions which Denton *et al.* (*Antarctic J.*, **5**, 15; 1970) set out to answer, at least partially, by an investigation of the ice-free zones in the region of McMurdo Sound, Victoria Land. This is a unique area for a study of glacial history in that it is a melting pot for no less than three major glacial systems (see map). First, the East Antarctic ice sheet is dammed west of the Transantarctic Mountains, although two small tongues of the ice sheet, the Taylor and Wright Glaciers, spill over into the western ends of glacially carved valleys. Second, in the east the Ross Ice Shelf floats on the surface of the Ross Sea. And finally, between the two glacial systems, occur independent alpine glaciers.

Denton and his colleagues have tried to compile a chronology for the three-glacier system which is, as far as possible, absolute, and they have been fairly successful. The various advances and recessions of the ice were, of course, deduced from a systematic examination of the glacial erosion features through the McMurdo Sound region. The dating of these changes was more difficult, because it depended much more on luck. Thus in some cases it was necessary to set glaciation limits in time by the potassium–argon dating of lavas and volcanic cones erupted between two glacial periods. In other cases, carbon-14 ages on shells in marine beds, freshwater algae in moraines or mummified seals resting on ice-free surfaces were used likewise.

The principal conclusion to emerge was that the huge ice sheet in East Antarctica had attained a "full-bodied stage" at least 4 million years ago. The build-up of ice and the corresponding 55 m fall in sea level must



therefore have occurred during or before the Pliocene. Other evidence has shown that West Antarctica was largely covered by an ice sheet by the late Miocene; and since the conditions necessary for this almost certainly prevailed in the east, too, it seems likely that the East Antarctica glacier had also been established by that time. This would presumably explain why eustatic sea level began a rapid decline during the Miocene. On the other hand, Tertiary sea level data give no indication of polar ice sheets before the Miocene. But this is not conclusive evidence; and the question of whether large glaciers existed in Antarctica before the Miocene remains open.

During the past 4 million years the Taylor–Wright glacier system has fluctuated in level several times, although the changes bore no relation to world-wide glaciations. At the moment the level is rising; and the ice is at its maximum height since before the Wisconsin glaciation as defined elsewhere in the world. Four Ross Sea glaciations can be recognized, all occurring within the past 1·2 million years. The recession of the most recent of these coincided with the rapid rise in sea level during the Late Wisconsin, but it is unlikely that this apparent correlation was climatically controlled because alpine glaciers in the area diminished in size during Ross Sea glacial advances. Further, the major Ross Sea glaciations were not synchronous with changes in level of the East Antarctic ice sheet. It is becoming clear that the three glacial systems in the McMurdo Sound area have fluctuated completely independently of each other.

CARBON

Glassy and Fibrous

from our Materials Science Correspondent

For some years, and especially since the Parliamentary Select Committee's report last year, attention in Britain has been focused on carbon fibres made by the British process developed at the Royal Aircraft Establishment. Much anguish has been aroused in political, engineering and industrial circles by uncertainties as to the proper manufacturing scale, price and applications of these fibres. The uncertainties are not eased by the fact, not widely recognized, that there are competing carbon fibres with an inferior technical specification but also a lower price.

Kawamura and Jenkins, who work at University College, Swansea, have described recently (*J. Materials Sci.*, **5**, 262; 1970) a new glassy carbon fibre made by pyrolysis of hexamine-tetramine dissolved in phenol, extruded to form threads. The extrusion and carbonization stages seem to be very simple and involve temperatures no higher than 1,000° C. A maximum tensile strength of 2 GNm^{-2} (3×10^3 pounds/inch^2) and Young's modulus of 70 GNm^{-2} (10×10^6 pounds/inch^2) for fibres 5 μm in diameter are reported. The raw materials can be derived from coal or oil tar fractions and the method has been patented by the National Coal Board.

There has been intensive development of a somewhat similar fibre in Japan, by the Kureda Chemical Industry Co. Ltd, based on unspecified "hydrocarbon pitch", particularly during the past year. This, and related work on other forms of carbon fibre, have been described in a recent survey by A. J. McLaren (*Design Engineering*, 109; February 1970). The carbonization temperature in the Japanese process is again about 1,000° C. The mechanical properties quoted are similar to those of the Swansea fibre, though the strength seems to be somewhat lower, and the fibre, presumably glassy, can be heat-treated to graphitize it; the properties of graphitized fibre are not mentioned. Kureda has now constructed a 120 ton plant (per annum output is presumably meant), and McLaren has listed several current applications including those depending on the low friction and wear associated with carbon fibre composites, and not requiring high stiffness. Some uses are distinctly unexpected: thus a large tonnage use is predicted for low-grade carbon fibre in carpets made from artificial fibres. Apparently litigation-conscious American carpet manufacturers are afraid of claims arising from deaths of patients with weak hearts who shuffle across highly insulating carpets, build up a charge and perish when they touch a door handle.

Another related development is solid glassy carbon, usually called vitreous carbon, which is made by pyrolysis of an unspecified polymer. The material was first studied in Japan, but large-scale development to the industrial stage has been undertaken by Plessey in Britain and it is now commercially available. Vitreous carbon has remarkable chemical stability, extremely low porosity, low friction, adequate electrical conductivity and high hardness, and this results in several novel applications, especially in the electronics and process industries and in spare part surgery. The properties of vitreous carbon have been surveyed in detail and compared with those of competing materials, and various uses have been described recently by F. C. Cowlard and L. E. Westmore (*Design Engineering*, 49, 52; March 1970).

PLANETARY SCIENCE

Smooth Surface of Mars

from a Correspondent

Lunar mascons and the surface properties of Mercury, Mars and Venus evoked lively discussions at the NATO Advanced Study Institute on the Moon and planets held at Newcastle upon Tyne from April 9–16 (early sessions were reported last week, *Nature*, **226**, 212; 1970). Dr W. L. S. Sjogren (Jet Propulsion Laboratory, California) dealt with the mascons, anomalous areas of locally higher gravitational field revealed by analysis of the orbits of Lunar Orbiter craft. He described the latest reduction based on a dynamic fit of all Lunar Orbiter data. Good correlations were found, with the prominent circular maria, Mare Orientale, shown to have a small positive anomaly surrounded by an annular negative anomaly.

Several interpretations were proposed for this. Dr M. J. O'Hara (University of Edinburgh) suggested that the mascons formed by the filling of depressions with the liquid phase of partially fused rocks. Because this phase concentrates the high density forming elements, subsequent solidification would produce the anomaly. The melt would rise to the surface if its density, while molten, were less than that of the surrounding rocks. Dr P. R. Bell (Oak Ridge National Laboratory) alternatively proposed that the surface of the Moon was originally molten due to an early "superluminous" phase of the Sun. Major impacts during the solidification of this layer produced pits into which the still molten fraction flowed, the fill and ejecta combining to form a positive gravity anomaly. Mare Orientale formed too late to have filled in this way. Professor H. C. Urey (University of California at San Diego) agreed that the surface must once have been molten, but pointed out that the presence of the mascons was difficult to reconcile with a molten or nearly molten interior. The interior must have a high degree of strength, for a subsidence of only one or two kilometres should eliminate the observed anomaly.

Dr G. H. Pettengill (Arecibo Observatory) reviewed recent radar studies of the terrestrial planets. Mercury seems closely to resemble the Moon in surface properties. Venus seems, on average, to be much smoother, though at least six anomalously rough areas have been mapped. Several small areas with heights of 1·5 to 2·0 km above the surroundings have been located, but there seems to be no large-scale relief. Mars seems to be even smoother than Venus, although there are large local variations in backscattering efficiency. There is a significant correlation between areas showing high echo specularity and those with low visual albedo, and there is considerable large-scale topographic variation in the northern tropics (the southern tropics have not yet been studied). Looking to the future, Pettengill predicted that, given adequate funds, it should be possible by 1974 to obtain radar echoes from the Galilean satellites of Jupiter, while by 1975 a 4 km radar resolution on the surface of Venus might be possible.

The description by Dr B. A. Smith (New Mexico State University Observatory) of the location of the satellite Phobos on several frames obtained from the Mariner 6 and 7 missions to Mars was a highlight of the proceedings. Phobos seems to be elongated (approximately 22·5 by 17·5 km) and to have a geometric albedo of about 0·065. If this figure is accurate, Smith pointed out, Phobos has the lowest albedo of any known object in the solar system, with the possible exception of some areas of the lunar surface.

When attention focused on the giant planets, the chief topic of interest was the magnetic field of Jupiter and the circulation of its atmosphere. Dr R. A. Stokes (University of Kentucky) warned that it is possible that a fluorescent or cyclic process could act in the atmosphere of Jupiter to produce infrared quanta with a non-equilibrium distribution. Some reported monochromatic temperatures may thus be significantly higher than the translational temperature of the source gas.

PROTEINS

Straightening out α-Keratin

from our Biomolecular Structure Correspondent

To be proposed independently by two Nobel laureates (and while both were in their model-building prime) might reasonably be taken to promise longevity for any structural hypothesis. Indeed, the coiled-coil structure for the α-fibrous proteins has been with us for more than seventeen years and the analysis on which it was based has influenced thinking on many topics in biomolecular structural analysis. Nevertheless, during the past few years there have been increasing signs of fundamental difficulties in the detailed fitting of the observed diffraction from the α-proteins with a coiled-coil model, and also indications that alternative models might account for the data reasonably well.

The most recent alternative to the coiled-coil model is due to Parry (*J. Theoret. Biol.*, **26**, 429; 1970) and brings together two proposals previously only considered separately. The first, due to Fraser and MacRae, suggests that each of the two or three α-helices which form the strands of the rope-like structure of α-proteins has a segmented structure. Each segment is a piece of undistorted α-helix typically ~20 Å long and the distortion resulting from folding of the strand is assumed to be confined to the few amino-acids in the region of the protein chain between segments. The second proposal derives from the work of Elliott and his co-workers, particularly the observation that in the paracrystalline phase of poly-γ-benzyl-L-glutamate in dimethylformamide the peptide backbone has the normal undistorted α-helical conformation, but the benzene rings at the ends of the side chains are arranged with quite different symmetry. The most striking feature in the diffraction from this structure is its similarity to that from α-proteins which have been identified as coiled-coils. This is particularly surprising because in the synthetic polypeptide structure the α-helical backbone in all the molecules is undistorted and all the molecules are parallel.

The segmented structure for the α-helical strands in the multi-stranded rope model for α-proteins allows each strand to assume a conformation reminiscent of a coiled-coil except that all the distortion from folding is confined to the part of the protein chain between segments. If the segment is not too long the favourable packing of side-chains in neighbouring α-helices, which provided the rationale for the original choice of the coiled-coil parameters, is largely retained in assemblies of segmented strands. The diffraction to be expected from such structures is in promising agreement with the observed "coiled-coil" data, and, possibly more important, that the intensity distributions in various regions of the diffraction pattern can be varied largely independently of each other. But this ability to adjust the calculated diffraction in such a regal way might be more a sign of the over-abundance of parameters in structures of this type than that the analyses are necessarily on a convergent track. Not only is the length of the segment largely undefined, so too is the number of strands in the multi-stranded rope and also their relative direction. Further allowance for the effect on the scattering of disordered material surrounding the molecules is fraught with difficulties although some progress is promised in this direction.

PROTEINS

To Catch an Enzyme

from our Molecular Biology Correspondent

AFFINITY methods of dipping into a mixture of components and extracting only the one with the right activity are, conceptually, at least as old as immunology, but their full power and versatility are only now being properly exploited. The principle is obvious enough: a ligand, for example, is immobilized and used to trap the protein for which it is specific, or vice versa. Affinity chromatography has, for example, been central to the work of Anfinsen and his colleagues on the chemical synthesis of staphylococcal nuclease. A terminal peptide fragment can be split from the chain, which will reassociate non-covalently with the residuum of the molecule to give a fully active enzyme. Chemical synthesis of the sequence corresponding to the terminal fragment gives an impure product because of side reactions, but the functional article is recovered from the mixture by passage through a column to which the residual protein is covalently attached.

The same principle has now been adapted to the capture of affinity-labelled fragments of the same enzyme. In affinity labelling of active sites, a bifunctional molecule is added to the protein, one end being a specific ligand (for example, inhibitor) that attaches at the active centre, the other a group of high chemical reactivity, which will react with any suitable side chain within reach. Digestion of the protein labelled in this manner then produces fragments, one of which contains the label and at least part of the active site or its environs. Givol *et al.* (*Biochem. Biophys. Res. Commun.*, **38**, 825; 1970) have hit on a way of isolating the fragment which circumvents the tedium of peptide separation procedures. The point is merely that the fragment still contains the specific ligand group, and may therefore be trapped on a column of the selfsame enzyme. As an example of this quite general strategy they give the following: pancreatic ribonuclease can be affinity-labelled with a derivative of uridine monophosphate with a phenyldiazonium-containing group substituted in the sugar. This reacts specifically with a tyrosine residue by the mononucleotide-binding site. The enzyme thus labelled is reduced, alkylated and digested with trypsin. The mixture of peptides is passed through a column of agarose beads to which ribonuclease is covalently bound through its amino groups by a now standard procedure that has been used to produce matrix-bound, insoluble enzymes. The mononucleotide end of the labelled peptide binds to the enzyme, all other peptides are washed through and the trapped ligand is flushed out with dilute alkali, pure and concentrated. A similar procedure has been used to prepare a peptide fragment from affinity-labelled anti-DNP antibody.

The application of the method to the study of active site peptides of staphylococcal nuclease is by Wilchek (*FEBS Letters*, **7**, 161; 1970). The specific inhibitor is deoxythymidine diphosphate, and the bifunctional version of this is substituted at the phosphate by a bromoacetyl-*p*-aminophenyl group. The bromoacetyl function is very reactive and attaches to lysines. After reaction and fragmentation by trypsin, the peptides are passed through a column of the nuclease bound to agarose, and only the labelled fragment sticks. A phenyldiazonium derivative has also been used in the same way, and reacts with a tyrosine residue. The peptide fragment was identified in terms of the position of its sequence in the chain, and it bears the label at Tyr-115, whereas the other reagent attaches to Lys-48 and Lys-49.

A more conventional application of affinity chromatography has been used by Gribnau *et al.* (*Biochem. Biophys. Res. Commun.*, **38**, 1064; 1970) for isolation of a protein inhibitor of ribonucleases. This comes from rat liver, and its partial purification by conventional methods has been a laborious matter. Pancreatic ribonuclease, anchored to a carboxymethylcellulose matrix (now a commercial product), was used to catch the specific inhibitor in the liver homogenate. After washing through the extraneous proteins, the enzyme–inhibitor complex was dissociated by high salt concentration. The product showed high activity, and was homogeneous by gel electrophoresis. Ribonucleases are the scourge of biochemists who operate in the general area of protein biosynthesis, and the rat liver inhibitor may prove to be of no small practical value.

POLYAMINES

Mysterious Functions

from a Correspondent

FORTY years after the election of S. O. Rosenheim to the Royal Society for discovering spermidine, and clarifying both its structure and that of spermine, the functions of these compounds and of their precursor, putrescine, are beginning to be understood. Recent advances in their physiology and biochemistry were discussed at a conference held on April 9 and 10 by the New York Academy of Sciences.

Drs A. B. Pardee and M. Inouye (Princeton University) described how putrescine and spermidine act in the synchronization of the division of amino-acid-deficient bacterial mutants. Dr W. K. Maas (New York University) described how division of putrescine-requiring strains of *E. coli* was selectively arrested in the absence of exogenous putrescine and spermidine. The genes for several steps in putrescine biosynthesis are clustered, suggesting that there is an operon for this function. Dr D. R. Morris (University of Washington) described the network of constitutive and inducible enzymes of putrescine biosynthesis in *E. coli*. The production of putrescine is subject to coarse controls of repression and derepression, and to fine controls of feedback inhibition and substrate availability. Dr S. S. Cohen (University of Pennsylvania) described the production of abnormally large amounts of spermidine in relaxed bacteria and of putrescine in organisms deficient in potassium ions. The latter phenomenon, which also occurs in plants, although involving different mechanisms of enzyme imbalance, was suggested by Dr T. A. Smith (Long Ashton Research Station, Bristol) to indicate the existence of a homoeostatic mechanism operative in acidic soils or those deficient in potassium ions.

Dr L. Stevens (King's College, London) showed spermidine and spermine to be bound to cellular ribosomes. These polyamines were found by Cohen in tRNA isolated at low ionic strength. Detection in tRNA involved a new sensitive fluorometric method described initially by Dr A. S. Dion and Dr G. J. Herbst (University of New Hampshire) in their work on the development of *Drosophila*. Dr J. R. Fresco (Princeton University) described the conversion of an inactive form of tRNA to an active configuration by three molecules of spermidine per molecule of the nucleic acid. Dr P. S. Leboy (University of Pennsylvania) indicated that polyamines could activate a tRNA methylase.

A developmental event involving an increase in RNA always parallels synthesis of spermidine. Dr A. Raina (University of Helsinki) and Dr S. H. Snyder (Johns Hopkins University) have shown that the early synthesis of spermidine and RNA in regenerating rat liver is anticipated by the specific stimulated synthesis of ornithine decarboxylase and of its product, putrescine. Dr A. E. Pegg (Courtauld Institute, London) and Dr H. G. Williams-Ashman (University of Chicago) have solved the problem of spermine synthesis by demonstrating a double-headed enzyme which decarboxylates S-adenosyl methionine in the presence of putrescine, and then transfers an aminopropyl moiety to putrescine and spermidine to form spermidine and spermine, respectively.

Dr C. M. Caldarera (University of Bologna) demonstrated similar correlations in embryonic systems. These enzymes are reported to have the shortest half lives (less than thirty minutes) of any described in mammalian tissues; this seems to relate to their rapid disappearance when rapid growth ceases. The finding that neither enzyme is produced in anucleolate *Xenopus laevis* suggests a possible integration of nucleolar function in the elaboration of both the ribosomal RNA necessary for growth and the polyamines tied to that RNA.

PROTEINS

Links in the Tissue

from a Correspondent

MEMBERS of the Collagen Club met on April 3 at the Meat Research Institute, Langford, to discuss the chemistry of the cross link in connective tissue proteins. In collagen and elastin intermolecular cross links in particular confer valuable physical properties. Dr S. M. Partridge (MRI) spoke about cross linkages in elastin. It was Partridge and his colleagues, of course, who in 1963 isolated the amino-acids desmosine and isodesmosine from hydrolysates of bovine ligamentum nuchae and, later, of aorta. On the basis of analytical data and electron microscopy, Partridge suggested that a suitable model for elastin was an arrangement of hydrophobic globular "pro-elastin" particles of mass 67,000, connected to each other by desmosine molecules. Such a model would account for results obtained by Dr D. P. Mukherjee (Massachusetts Institute of Technology), who has examined the visco-elastic properties of elastin. Dr S. O. Anderson (University of Cambridge) had studied heat changes of elastin on stretching and his findings could also be explained by Partridge's proposed particulate structure.

In spite of considerable differences in chemical composition and properties between elastin and collagen, Dr R. A. Grant (ARC Institute of Animal Physiology, Babraham) claimed evidence for similarities in the primary structure of these two proteins. When heat-shrunk collagen was treated with elastase and the released neutral peptides were subjected to fingerprinting, the pattern obtained resembled that of elastase-treated elastin, but was different from that of elastase-treated ovalbumin and of bovine serum albumin. Elastase-treated collagen α_1 and α_2 chains also gave similar patterns. Grant suggested that elastin and collagen contained certain common amino-acid sequences.

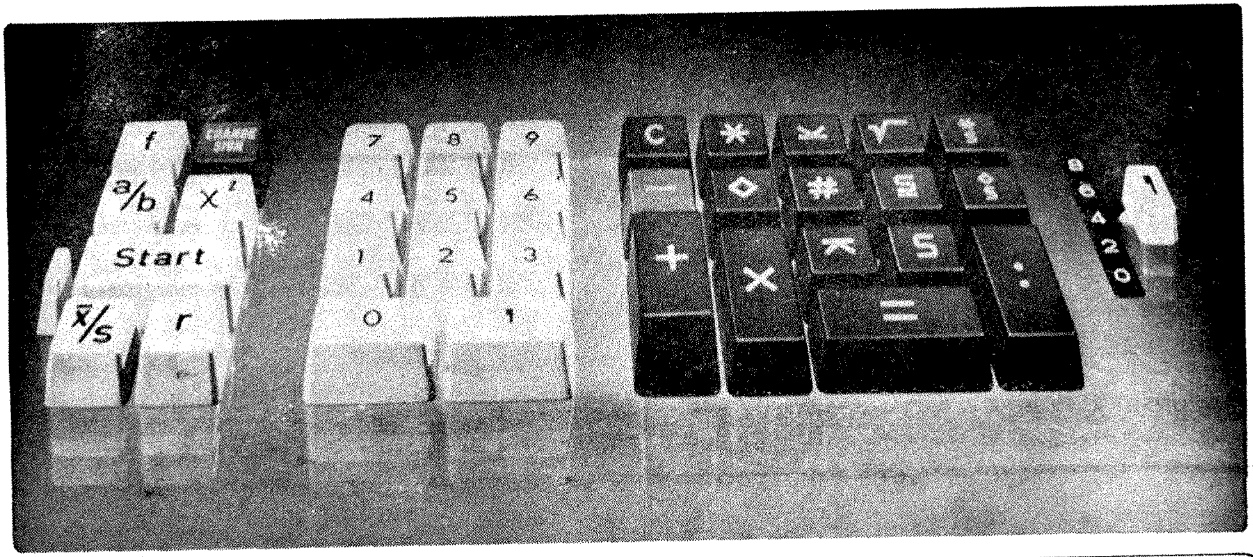
Although various interchain cross links have been postulated for collagen, those derived from lysine aldehyde are well established. Dr A. J. Bailey (MRI) provided evidence that this type of linking occurred intermolecularly. As in elastin, a lysine residue was first converted by amine oxidase to aldehyde. The aldehyde could react with a group of another residue suitably positioned to form an interchain cross link. Various cross links could therefore be produced, some of which were labile and would not survive hydrolysis conditions. If, however, they were reduced with borohydride the cross links were converted to stable derivatives. Hydrolysis followed by amino-acid analysis would reveal the presence of a new amino-acid derived from the reduced cross link, which if identified would provide evidence for the nature of the original cross link. If tritiated borohydride was used for reduction, measurement of radioactivity in the amino-acid chromatogram peaks would provide a measure of the number of residues involved in cross linking. As an example, the production of hydroxylysinonorleucine after reduction indicated that the native cross link was formed by a hydroxylysine-derived aldehyde condensing with an amino end group of a lysine side chain to form a Schiff base.

Dr L. J. Fowler (MRI) described experiments which could provide important information about the biosynthesis of lysine-derived cross links. In lathyritic animals, collagen has a deficiency of cross links when analysed by the procedure described by Bailey. However, when bone collagen from lathyritic chickens was incubated with extracts of healthy chicken tibia and femur, a large increase of lysine aldehyde-derived constituent was observed, presumably due to amine oxidase extracted from the normal tissues. Similar results were obtained when lathyritic pig collagen was incubated with extracts of normal pig tissue. This type of experiment could be used for examining inhibition or enhancement of amine oxidase activity.

When collagen is irradiated with ultraviolet light it fluoresces bluish white, and some think that this is due to cross links derived from tyrosine residues. Mr C. McDevitt spoke about his work with Dr W. G. Armstrong at the Royal Dental Hospital, directed at isolating and examining this fluorescent material. Starting from ox femur collagen, they fractionated the fluorescent material in alkaline hydrolysates, but it was not dityrosine (which is fluorescent and present in resilin) because it differed in spectral characteristics and chromatographic properties. Tyrosine was probably involved, however, because when rats were fed on radioactive tyrosine, the fluorescent fraction from their collagen was radioactive and resembled that from the ox femur. The latter seemed to contain acidic groups and its chemical properties and mass spectra suggested that it was a derivative (probably pyrophosphate) of thiamine. It was not possible at this stage to say whether the thiamine was covalently linked with the collagen, but it seemed to be fairly firmly bound.

DIEHL sigmatron

Electronic Calculating System with Pre-programmed Statistical functions



DIEHL sigmatron is the first calculating system specifically designed for Statistical calculations.
By pre-programmed functions, Statistical calculations are reduced to one key operations. For instance, to obtain the Arithmetic Mean and Standard Deviation enter data on the keyboard and touch the pre-programmed key. After entry of the data is completed you need only touch the same pre-programmed key to obtain the results immediately. Linear Regression, Chi Square, Coefficient of Correlation are all reduced to the simplicity of one key operation.
DIEHL sigmatron also gives you a powerful and effective calculating performance with ten separate memories, automatic square root, automatic decimal selection up to 8 places and a complete check of each figure, each step and each result.
If you prefer to make your own programs, DIEHL combitron S has 10 Program/Memory registers providing a capacity of 120 steps with branching and looping.
For external input of data, DIEHL dilector – punched tape reader – is available.

Multiple-Beam Interference Microscopy of Metals

S. Tolansky *Royal Holloway College, University of London, Egham, Surrey, England*

March 1970, x + 148 pp., 45s. (£2.25) SBN 12.692650.6

This monograph is devoted to the use of multiple-beam interferometry for the study of metals, especially those used in engineering technologies. It gives the "know-how" of many years' study and use of the technique which will enable metals scientists and engineers to exploit the technique to advantage.

Contents Principles of multiple-beam interference. Multiple-beam localized fringes. Preparation of reflecting films. Microscope arrangements. The matching flats and fringe definition. Evaluation of topographic features. Efficiency of silver contour. Surface roughness: interference contrast. Hardness measurement. Thickness of thin films. Some applications. Historical object—Barton's button. Some studies on silicon carbide crystals. References. Appendix: fringes of equal chromatic order. Index.

Biochemical Society Symposium Number 29

Natural Substances Formed Biologically from Mevalonic Acid

Edited by T. W. Goodwin *Department of Biochemistry, University of Liverpool, England*

February 1970, x + 186 pp., 55s. (£2.75) SBN 12.289865.6

The discovery of mevalonic acid as a specific precursor of terpenoids revolutionized this field of biochemistry. This book represents a stocktaking, by world-famous authorities, of recent developments. It is essential reading for all research workers in the field and for senior undergraduate biochemistry students.

Contents Chairman's opening remarks. Chemistry of mevalonic acid. Conversion of mevalonic acid into prenyl hydrocarbons as exemplified by the synthesis of squalene. Enzymatic studies on the oxidative cyclizations of squalene. Sterol biosynthesis. Nature and distribution of terpene quinones. The biosynthesis of terpenoid quinones. Polyprenols. Biological function of terpenoid quinones. Terpenoids in insects. Biosynthesis of terpenoid alkaloids. Chairman's concluding remarks. Author index. Subject index.

Society for Applied Bacteriology Technical Series No. 4

Automation, Mechanization and Data Handling in Microbiology

Edited by Ann Baillie *Unilever Research Laboratory, Colworth House, Sharnbrook, Bedford, England*

and R. J. Gilbert *Food Hygiene Laboratory, Central Public Health Laboratory, London, England*

March 1970, xvi + 234 pp., 65s. (£3.25) SBN 12.073650.0

This volume brings together a number of time- and labour-saving techniques from different disciplines and indicates their potential usefulness, describing possible applications of automation, mechanization and data handling techniques to microbiology. This book will be of interest to microbiologists, clinical pathologists and students of microbiology and biochemistry.

Contents Computer identification of bacteria. A computer-linked data processing system for routine hospital bacteriology. Computer use in information and data handling. The application of some automation and data handling techniques to the evaluation of antimicrobial agents. Automated reading of large assay plates. Identification of bacteria with the aid of an improved information sorter. Applications of the Coulter Counter in microbiology. Fully automated high speed amino acid analysis. An automated technique for the determination of ammonia produced by bacteria. The POMEC—an apparatus for growing dense cultures of pathogenic micro-organisms. An automatic growth recorder for microbial cultures. Control of oxygen tension using the Mackreth electrode. Multiple inoculation technique for rapid identification of bacteria. A multiple dropper for micro-titration apparatus. Examples of mechanization in microbiology media service sections. Automatic methods in diagnostic bacteriology. Author index. Subject index.

The Yeasts, Volume 3: Yeast Technology

Edited by A. H. Rose *School of Biological Sciences, Bath University, Bath, England*

and J. S. Harrison *Research Department, The Distiller's Co. (Yeast), Ltd., Epsom, Surrey, England*

April 1970, xiv + 590 pp., 150s. (£7.50) SBN 12.596403.X

Yeasts have been associated more intimately than any other group of micro-organisms with the progress and well-being of mankind. In this volume specialists from universities, research and industry deal with yeast technology, each giving a detailed and balanced view of his or her own field of interest.

Contents Introduction. Yeasts in wine-making. The role of yeasts in cider-making. Brewer's yeasts. Saké yeasts. Yeasts in distillery practice. Baker's yeasts. Food yeasts. Yeasts as spoilage organisms. Miscellaneous products from yeasts. Author index. Subject index.

Control and Use of Scientific Information

by
HERBERT COBLANS
38 Oakways,
Eltham,
London SE9

Since 1966 Unesco and the International Council of Scientific Unions have been looking into the feasibility of a world science information system. Dr Coblans, a member of the committee concerned, gives a progress report on the project at a crucial stage in its history.

THE concept of a world centre conserving all documents and serving everyone has long been a recurrent theme. Even though there have been brave attempts at its realization, it was clearly Utopian. A typical attempt was the International Catalogue of Scientific Literature for the twentieth century, sponsored by the Royal Society and abandoned in 1922 after a subject catalogue for the literature of the first fourteen years of the century had appeared. The attempt to establish a world bibliographical centre for "education, science and culture" by Unesco in Paris in the late nineteen-forties did not survive the first stages of planning and implementation.

Nonetheless, Unesco by its constitution and purpose has a basic responsibility in this field, and it is therefore right and proper that, jointly with the International Council of Scientific Unions (ICSU), it should be investigating the feasibility of UNISIST, a phonetic invention to symbolize the part which the United Nations (UN . . .) should take in promoting a world-wide system (. . . SIST) of information, both scientific and technical (. . . IST). It should be stressed that this time there is no suggestion of a vast central bureau, but rather the coordination and interconnexion of existing networks, chiefly national, based on voluntary cooperation and the standardization essential for the exchange of documentation and information.

At the General Conference of Unesco held in 1966, a common programme was approved under the title "Joint ICSU–Unesco project in the communication of scientific information and on the feasibility of a world science information system". A working party met shortly afterwards to define the broad outlines and the implementation of the proposed study. As a result, a central committee* was created and this has met four times since December 1967. The project has now reached a crucial point, for the draft report, prepared by Dr J.-C. Gardin, was considered and accepted at the fourth session which was held in December 1969.

Working Groups

The central committee has worked principally through six working groups to which specific tasks have been delegated: evaluation, compression and organization of scientific information; indexing and classification; bibliographic descriptions; language problems; research needs in documentation; scientific information in developing countries. In addition, the committee has had the benefit of the comments and criticisms of an advisory panel of nine representatives (present as observers) of large working services such as MEDLARS, Euratom, the American Chemical Society and the Information Service in Physics, Electrotechnology, Computers and Control (INSPEC).

Of all these working groups, that concerned with bibliographic descriptions is the most important at present and has been the most productive during the two years of its operation. The reason is simple—there can be no real world transfer of scientific information to the general benefit of all countries, whether industrially advanced or developing, unless there is a minimum of standardization in the "language" of communication. In certain topics where a meta-language of symbols exists (for example, in mathematics, organic chemistry, classical taxonomy) the literature of science is truly international, but even here the problems of machine storage and print-out remain to be solved economically, although prospects are very encouraging. But, even if the content of a scientific paper is thus understood by fellow scientists the world over, its identification and description as a bibliographical unit are at present based on a somewhat chaotic set of conventions arising from national and language practices that are chiefly historical in origin. Whatever else the use of computer methods in documentation has achieved, it has made it abundantly clear that there can be no real economies and progress unless magnetic tape stores and the related computer-aided printing are reasonably compatible and interchangeable and therefore exchangeable.

This essential standardization is the responsibility of the International Organization for Standardization (ISO), a federation of national standardizing bodies which makes international recommendations which are subsequently translated into national standards. Inevitably ISO can only work slowly because its recommendations must be circulated to all member states for comment. What emerges is all too often a compromise, theoretically defensible, but not used much by the major services in abstracting and indexing or even less by the scientific press.

The working group on bibliographic descriptions started from the other end, and has looked at the daily practice of the large existing services, particularly those within the ambit of the ICSU Abstracting Board, and even more significantly those that are being computerized. By bringing these together and negotiating in areas where agreement on small changes is not difficult to achieve, UNISIST has begun to have some success. Once these standards have been accepted by the large services, chiefly international in scope, there is every chance that ISO will manage to promulgate them as recommended international standards.

At the meeting of UNISIST last December, this work was reported to be fairly well advanced in three areas. First, there is the question of essential information for the control of periodical literature (some fifteen elements). In each case this requires identification of the periodical, the specific issue, the paper within the issue, the "author" responsible for the publication and the language. This involves the accepted abbreviations of words in periodical titles in all languages for each periodical title. Thus a UNISIST list of abbreviations will have to be kept up to date. Similarly a world register for scientific and technical periodicals, a very large undertaking, is proposed. It would provide a machine file of periodical titles and standard serial numbers (SSN) on the analogy of the widely accepted standard book numbers (SBN). This would make possible a unique identification code for all documents (papers, reports and so on) with information value. The practices of citing the names and affiliations of authors, for most of the countries publishing literature, have been analysed and a set of recommendations will be tested for suitability.

---

* Chairman: Dr Harrison Brown (foreign secretary, US National Academy of Sciences, Washington, representing ICSU). Members: Dr B. W. Adkinson (USA), Eng. N. B. Arutyunov (USSR), Professor G. A. Boutry (France), Dr H. Coblans (UK), Dr H. T. Hookway (UK), Professor H. Kaiser (Federal Republic of Germany), Professor M. Kotani (Japan), Professor A. I. Mikhailov (USSR), M. P. Piganiol (France), Dr F. A. Stafleu (Netherlands). Unesco representative: Dr A. Pérez Vitoria, later replaced by Dr A. Wysocki. The original membership also included Dr P. Lazar (Hungary) and Dr C. Sherwin (USA), who resigned for various reasons and were replaced by Professor A. Avramescu (Rumania) and Dr Milton Harris (USA). Observers: the sessions have been attended by representatives from more than twenty international organizations, all directly involved in documentation and information transfer.

Second, on the question of transliteration, the ISO standard for Cyrillic alphabets is internationally accepted for scholarly use, but the diacritical marks are not handled easily on computers. By agreement with the All-Union Institute of Scientific and Technical Information (VINITI) in Moscow, an international standard avoiding the use of diacriticals has been proposed. Similarly, conventions have been worked out for the special letters used in Germanic and other languages.

The third line of advance concerns character sets and encoding systems. The importance of compatibility for merging duplicate tapes in information retrieval systems and the computer-aided printing of lists is widely understood, but remains a serious obstacle. It was agreed to start from a basic set of forty-five characters (Roman capitals, ten digits and nine additional characters). An inventory of additional characters used by most large services is being drawn up. Each character not in the basic set will be encoded by the use of two or more of the basic characters. Another important, but somewhat intractable, standard remains to be studied—the sorting order of the character set. The recommendations and standards I have described have received agreement from all the member services of the ICSU Abstracting Board, as well as several international organizations, and they propose to implement them progressively. This would have seemed Utopian even a few years ago.

Voluntary Cooperation

The other working groups by their nature were not able to act so effectively; their function has been to analyse, to define the problems and to sound out informed opinion at all levels on as international a scale as possible. In a sense the draft report prepared by Gardin has provided a statement of the present position and a synthesis of what has emerged from the activities of the working groups and the central committee. The assumptions of such a world science information system are summarized as follows in the report.

(*a*) Scientific and technical information, as embodied mainly in the more formal printed sources, is the property of all nations; (*b*) this printed literature, published or unpublished, can be considered for this reason as a collective store, from which information is to be extracted, organized, processed, evaluated, re-packaged, etc., in a variety of ways, by the concerted effort of all countries; (*c*) these operations in the "transfer chain" are best performed through a worldwide division of labour between all parties, with due consideration but no necessary subjection to existing geopolitical divisions; (*d*) the output from each party, at any stage of transfer, can then be made available as input to other parties, subject to the acceptance of common standards; (*e*) such standards are well within our reach, provided proper mechanisms be set up to hasten their definition, ratification and implementation by all parties.

The central committee has tried to harmonize the varying needs and assign priorities for such a decentralized system of voluntary cooperation among existing and future services in various countries and regions, languages and disciplines. Such an inventory would include, first, bibliographic and machine standards. These would be internationally accepted and used, with a central coordinating office to maintain them and develop new ones throughout the UNISIST community and speed up formal ratification through ISO. Second, there would be specification of subject content and information retrieval. This is the most complex problem of documentation because it demands much more research into the use of general classifications, the evaluation of indexing languages, the construction of compatible thesauri and standard lists of subject headings. Third, the inventory would include linguistic and semantic problems. These arise in the machine processing of scientific texts especially for automatic indexing; in on-line "dialogue" between user and computer; for indexing by free text searching for words; and, most difficult of all, for machine translation. And, fourth, would be the needs arising from the fact that if developing countries are to benefit from what UNISIST can potentially offer, they must be able to reach a basic level of requirements. This would include at least two types of resources, books, periodicals and so on, and reference tools for their utilization located in professionally staffed libraries, and a nucleus of technical manpower at a level appropriate to the size and development objectives of the country. To help in providing these needs, and above all in the training of the necessary staff, the United Nations Development Programme will be asked to make funds available for the creation, under international control, of several regional centres as pilot projects in carefully selected areas. These would act as clearing houses for local and external documents; as centres for the education and training of information personnel and also the users of information; as the focal points for the international exchange of information and the exploitation of mechanized stores in the form of duplicate magnetic tapes.

While there was general agreement on the basic principles of the draft report, there remain several partly resolved questions, which are inherently difficult. The principal difficulty concerns national languages, the subject scope of UNISIST and the form of its organizational structure when it comes into being.

Language Problems

Governmental international organizations tend to work in the four or five languages which dominate international communication and discourse. This is even more marked in some of the natural sciences; for example, in physics and chemistry, comprehensive abstracting services are more and more appearing only in English, Russian and French. Here the hard facts of economic life are determinant. On the other hand, several national representatives feel strongly that language should not be used as a sort of "colonial" weapon. They argue that, because language is a fundamental component of each national culture, Unesco should promote the development of national languages, particularly in African and Asian countries. This clearly complicates the problems of UNISIST, which is already faced with the negative effects of language barriers on the flow of information.

An attractive proposal has been that each developing country, while fostering its own local language, should choose a major language as its "language of transfer".

UNISIST has evolved from a joint initiative of Unesco and ICSU and as such has stressed the natural sciences as the starting point, hoping to move progressively into the technological fields. Strong voices are insisting that from the beginning UNISIST should cover not only the pure but also the applied sciences, for from the point of view of information they cannot really be disentangled. Science and technology are being more and more affected by social and economic considerations as science policy and management become accepted as national imperatives. Therefore the separation of pure, applied and social sciences, especially from the point of view of information, is no longer realistic and efficient.

The third question is clearly controversial: what kind of organization can handle—coordinate and lead—so varied a conglomeration as governments, non-government organizations, learned societies, universities, industrial units? The draft report convincingly shows that UNISIST is feasible and necessary. Therefore the next steps must be to find the financial resources and create the administrative machinery for implementing and maintaining such a world-wide system of cooperation. To do this, Unesco, jointly with ICSU, is planning an international conference to be held probably in the last quarter of 1971 to bring together about 300 scientists, information specialists and government officials responsible for research and information policy. For this conference the final report on feasibility will be the working paper.

Administrative Structure

One suggested administrative structure, on the model of the very effective Intergovernmental Oceanographic Commission, is an International Commission for Scientific Information. Such a commission combining government, professional and user interests would indeed be a breakthrough. For the first time there would be a central steering body capable of evaluating, interpreting and then presenting to governments and others what can and must be done now, and furthermore with the executive strength to act. So far we have had no such overall and accepted body with the status and the power to do this. There are numerous international organizations each active in its own way: Unesco organizing documentation centres for developing countries, ISO promoting standards for documentation, WHO and FAO taking some responsibility for documentation in certain subject fields, OECD stimulating science information policy at the national level, ICSU coordinating abstracting services, FID furthering documentation at the professional level and so on. No organization has had the mandate and the resources to steer these multifarious activities and act on limited agreement. Nowhere are these problems seen and acted upon as a whole in all their intricate inter-relationships. By and large, the result has been an ineffectual Babel and therein lies our information crisis!

Characterization of Ovine Hypothalamic Hypophysiotropic TSH-releasing Factor

by
ROGER BURGUS
THOMAS F. DUNN
DOMINIC DESIDERIO*
DARRELL N. WARD†
WYLIE VALE

Department of Physiology, Baylor College of Medicine, Houston, Texas 77025

Evidence is presented for the homogeneity of a preparation of hypothalamic TRF of ovine origin and its molecular structure has been established as 2-pyrrolidone-5-carboxylyl-histidyl-proline amide. Synthetic L-2-pyrrolidone-5-carboxylyl-L-histidyl-L-proline amide has physicochemical and biological characteristics which are quantitatively and qualitatively indistinguishable from those of the natural substance isolated in this laboratory.

THE existence of hypothalamic thyrotropin (TSH) releasing factor was demonstrated in 1962 (ref. 1). Recently[2] we obtained a highly purified preparation of hypothalamic TRF (acetate) of ovine origin according to the purification sequence summarized in Table 1 and demonstrated by analysis of a 6 M HCl hydrolysate that it contained as much as 81 per cent of its molecular weight in terms of the three amino-acids, glutamic acid, histidine and proline in equimolar ratios (theoretical contribution of the three amino-acids for a tripeptide acetate = 86 per cent). No free N-terminus could be demonstrated in this preparation of ovine TRF by dansylation. We subsequently reported that fully synthetic tripeptides of the generic structure PCA-His-Pro-R (PCA = 2-pyrrolidone-5-carboxyl) but not Glu-His-Pro-R, had TRF activity qualitatively indistinguishable from that of natural TRF. The specific activity of the tripeptides increases in the order $R = OH < OCH_3 < NH_2$, PCA-His-Pro-NH$_2$ having a biological activity not statistically different from that of natural TRF obtained as above[3-5]. Furthermore, the physicochemical characteristics of the various synthetic tripeptides, and particularly of PCA-His-Pro-NH$_2$, were closely related to those of natural ovine TRF. On the basis of low and high resolution mass spectrometric studies of highly purified ovine TRF and of a pure preparation of synthetic PCA-His-Pro-NH$_2$ (ref. 6), we have proposed that the molecular structure of hypothalamic ovine TRF is PCA-His-Pro-NH$_2$ (ref. 7).

We report here the detailed evidence on which this statement was based as well as information on (1) the nuclear magnetic resonance (NMR) spectra of pure ovine TRF and the synthetic tripeptide-amide; (2) quantitative amino-acid and ammonia analyses of natural ovine TRF and the two synthetic tripeptides PCA-His-Pro-OH and PCA-His-Pro-NH$_2$; (3) the biological activity of pure

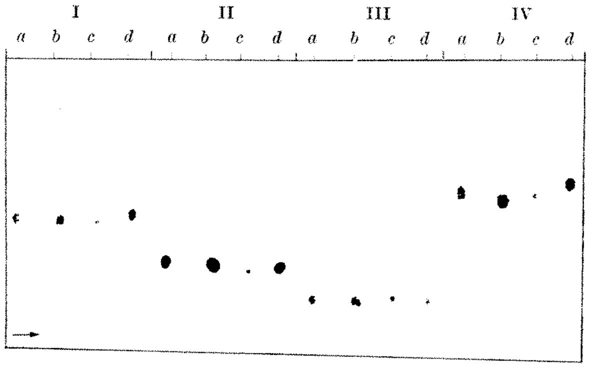

Fig. 1. Thin-layer chromatography of (*a*) 5 μg PCA-His-Pro-NH_2 prepared by total synthesis; (*b*) a mixture of 5 μg PCA-His-Pro-NH_2 prepared by total synthesis and 2·5 μg natural ovine TRF; (*c*) 2·5 μg natural ovine TRF; and (*d*) a mixture of 2·5 μg PCA-His-Pro-NH_2 prepared by total synthesis and 2·5 μg PCA-His-Pro-NH_2 prepared by ammonolysis of the methyl ester of PCA-Glu-His-Pro-OH. Thin-layer chromatography was performed on silica gel G (Eastman 'K 301 R2') in the systems: I, *n*-butanol–ethyl acetate–acetic acid–water (1 : 1 : 1 : 1); II, *n*-butanol–acetic acid–water (4 : 1 : 5); III, *n*-butanol–ethyl acetate–0·2 M aqueous NH_4OH (1 : 1 : 2); IV, collidine–ethanol–diethylamine–water (220 : 100 : 1 : 80). The upper phase was used in the case of two phase systems.

ovine TRF compared with synthetic PCA-His-Pro-NH_2. The new data support our earlier conclusions and prove that the tripeptide derivative PCA-His-Pro-NH_2 prepared by ammonolysis of the methyl-ester of PCA-His-Pro-OH[4,5] or prepared by total synthesis[6] has characteristics practically identical to those of natural ovine TRF and a biological activity which is not statistically different.

Physicochemical Characterization

Mixtures of 2·5–5·0 μg aliquots of natural ovine TRF and synthetic PCA-His-Pro-NH_2 move as a single spot as stained by the Pauly reagent in several chromatographic systems (Fig. 1).

For the examination of infrared spectra, 50 μg of natural ovine TRF (acetate) and of synthetic PCA-His-Pro-NH_2 (acetate) was deposited as thin films on the window of an 'Irtran' cell; spectra were observed in a Beckman 'IR-9' spectrometer. The spectra of the two materials (Fig. 2) are identical at all wavelengths with the exception of a peak at 1,110 ± 9 cm^{-1} (mean of six independent experiments) in the spectrum of synthetic PCA-His-Pro-NH_2 which is displaced to 1,121 cm^{-1} (mean of three independent experiments) in the spectrum of natural ovine TRF. This minor discrepancy, although observed with two different batches of TRF, is not statistically significant. Studies with a series of synthetic analogues of the generic structure PCA-His-Pro-R have indicated the possibility of producing such minor shifts by changing the *p*H of the solution(s) deposited on the 'Irtran' cell; the presence of traces of metal(s) chelated by either peptide may also be a possible explanation. We consider the similarities of the two spectra to be sufficient to indicate identity.

Table 1. SEQUENCE OF PURIFICATION FOR ISOLATION OF OVINE TRF

Stage	No. of fragments × 1,000*	Weight†	TRF units/mg‡
1. Lyophilized sheep hypothalamus	294	25 kg	
2. Alcohol–chloroform extract	294	294 g	1
3. Ultrafiltration 'UM-3'	294	71 g	3
4–5. Gel filtration, 'Sephadex *G*-25', 0·5 M acetic acid, 2X	286	16 g	16
6–7. Partition chromatography, 0·01 per cent acetic acid–*n*-butanol–pyridine (11 : 5 : 3), 2X	280	246 mg	800
8–9. Adsorption chromatography, Norit/H_2O–ethanol–phenol, 2X	275	4·2 mg	30,500 (1,100–200,000)
10. Partition chromatography, *n*-butanol–acetic acid–H_2O (4 : 1 : 5, upper phase)	273	2·0 mg	58,500 (12,500–150,000)
11. Repeat 10	270	1·0 mg	57,000 (12,000–124,000)

* Number of hypothalamic fragments available at each step in the purification sequence; the continuous decrease in number from step 4 to 11 results from the removal of aliquots for pilot studies, repeated bioassays, and so on.

† From step 3 to 11, the weights correspond to those of the TRF-active fractions at each step.

‡ Specific activity (TRF U/mg) with 95 per cent confidence limits in multiple four-point assays.

Low resolution mass spectrometry was performed on 20–40 μg samples of ovine TRF from stage 11 (Table 1) and of synthetic PCA-His-Pro-NH_2 which were methylated by treatment with an excess (50 μl.) of a solution of diazomethane in diethyl ether (3 × 5 min). Similar aliquots were also derivatized by treatment with 50 μl. of a 1 : 1 mixture of trifluoroacetic anhydride and trifluoroacetic acid (1 h, room temperature). Figs. 3 and 4 illustrate the low resolution spectra of the products. All samples were volatile in low resolution mass spectrometry (LKB 9000, direct probe, $\leq 10^{-6}$ torr) at probe temperatures ranging from 150°–200° C. Several mass spectra for each sample (seven in the case of TRF derivatives), recorded at various temperatures along the programmed thermal gradient, yielded identical fragmentation patterns corresponding to a single chemical entity. Combined with other evidence (quantitative amino-acid content[2], nuclear magnetic resonance spectra, thin-layer chromatographic data) these results allow us to claim the preparation, for the first time, of a hypothalamic hypophysiotropic releasing factor.

The mass spectra of the same derivatives (trifluoroacetylated or methylated) of natural ovine TRF and synthetic PCA-His-Pro-NH_2 are essentially identical (Figs. 3 and 4). No molecular ion was observed in any of these spectra; similar fragments were observed in the low resolution spectra of each derivative of natural TRF and synthetic PCA-His-Pro-NH_2. Ions were observed corresponding to the following structures: PCA, *m/e* 84; PCA + CH_2, *m/e* 98; His, *m/e* 94; His + CH_2 *m/e* 108; Pro minus 3H, *m/e* 93; Pro-NH_2 minus 3H, *m/e* 110 (unsaturated proline fragments such as pyrrole-2-carboxamide possibly produced by pyrolysis); $CONH_2$, *m/e* 44; PCA-His, *m/e* 221; His-Pro-NH_2 minus 2H, *m/e* 248. Other fragments, *m/e* 234, 235 and 249, could arise from PCA-His, His-Pro-NH_2 or also, as Schally *et al.* mentioned in the case of a preparation of porcine TRF[8], from the diketopiperazines of histidine and proline.

The elemental composition of all these fragments, except ion *m/e* 221 which was too weak to give a readable trace on the photoplate (Ilford 'Q2'), was confirmed on the methylated derivatives of TRF and synthetic PCA-His-Pro-NH_2, using high resolution mass spectroscopy ('CEC 21-110') (Table 2).

For nuclear magnetic resonance (NMR) spectrometry,

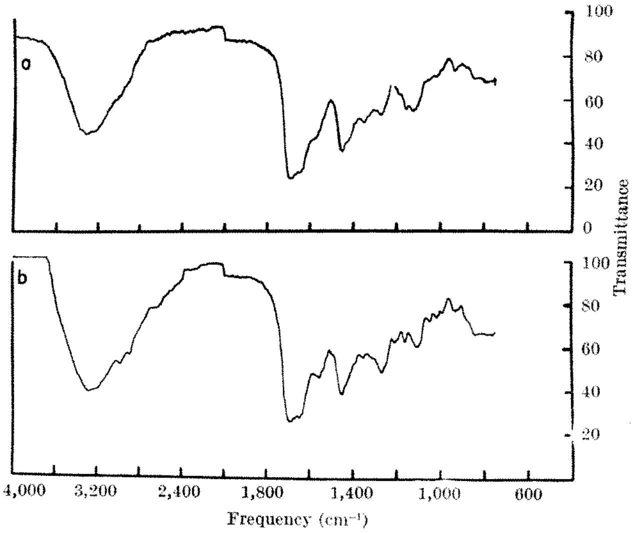

Fig. 2. Infrared spectra of (*a*) isolated ovine TRF and (*b*) synthetic PCA-His-Pro-NH_2.

0·8 mg of ovine TRF acetate (stage 11, Table 1) was dried in a 5 mm NMR tube and redissolved in 200–300 µl. ^2H_2O. The NMR spectrum of this preparation was obtained using a 100 MHz spectrometer (Varian 'HA-100') with time averaging by coupling to a computer of average transients ('C-1024'). Fig. 5*a* shows the spectrum, in comparison with a single sweep spectrum (Fig. 5*b*) of 25 mg synthetic PCA-His-Pro-NH_2 (acetate) as a solution in a similar volume of ^2H_2O using the same spectrometer. In the regions that can be compared, the spectra of the two compounds are practically identical. The singlet at 3·5 p.p.m. present in the TRF spectrum but absent in that of the synthetic compound may represent a minor impurity, but could also arise from a spinning side-band of the peak for water. The slight differences in the location of the maxima in the 7–9 p.p.m. region, presumably from the histidine ring protons, can be explained by the *p*H sensitivity of these bands in histidine NMR spectra[9].

Histidine and ammonia contents were determined in TRF and synthetic analogues, and the results are given in Table 3. Quantitative analyses of 6 M HCl hydrolysates of ovine TRF, synthetic PCA-His-Pro-OH, synthetic PCA-His-Pro-HN_2 and unhydrolysed TRF were obtained using a Beckman-Spinco modified model '120C'. The figures obtained for ovine TRF correspond to the presence of an amide group on the C-terminal proline.

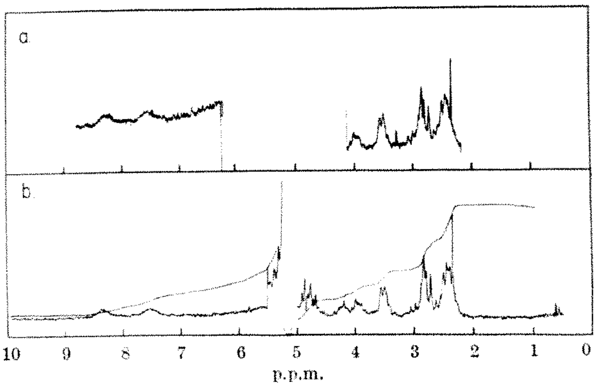

Fig. 5. Proton magnetic resonance spectra (100 MHz) of (*a*) ovine TRF acetate in ^2H_2O, time-averaged for 276 scans, 500 s/scan, 500 Hz sweep width in the regions shown, lock signal internal H^2HO (5·14 p.p.m. referenced to external capillary of tetramethylsilane in a separate experiment); (*b*) synthetic PCA-His-Pro-NH_2 (acetate) in ^2H_2O, single scan 1,000 s, sweep widths 1,000 Hz; referenced to external capillary of tetramethylsilane. Both spectra were obtained at 31° C.

Biological Activities

Using an *in vivo* mouse assay[5], six independent four-point assays of homogeneous natural ovine TRF gave a specific activity of 55,000 ± 9,900 U/mg (see ref. 10 for the definition of the TRF unit); five independent four-point assays of synthetic PCA-His-Pro-NH_2 gave a specific

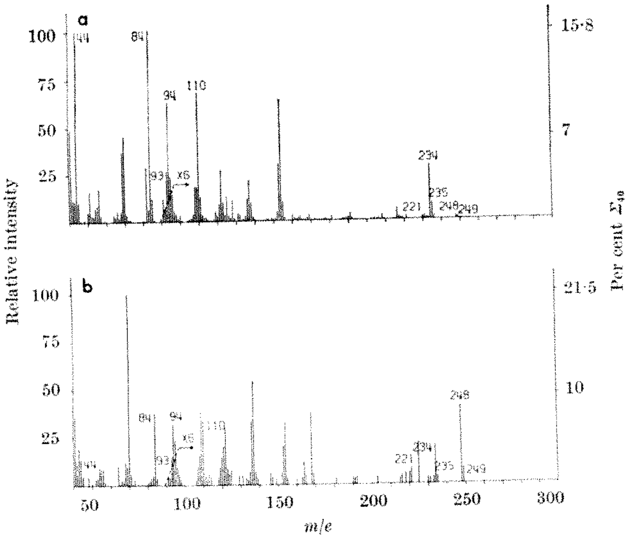

Fig. 3. Low resolution mass spectra of trifluoroacetylated ovine TRF (*a*) and synthetic PCA-His-Pro-NH_2 (*b*).

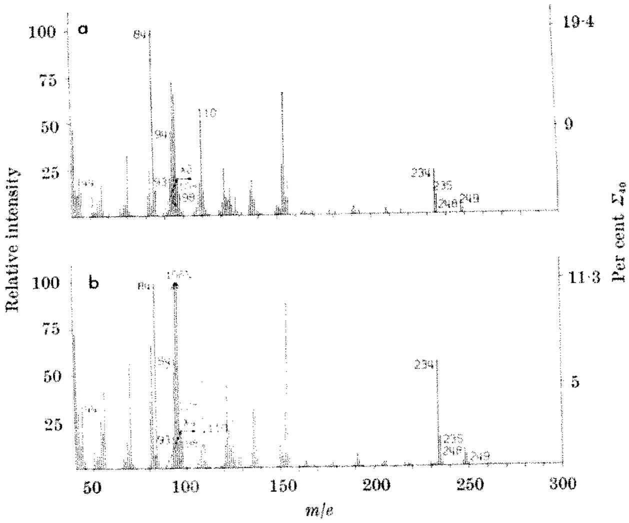

Fig. 4. Low resolution mass spectra of methylated ovine TRF (*a*) and synthetic PCA-His-Pro-NH_2 (*b*).

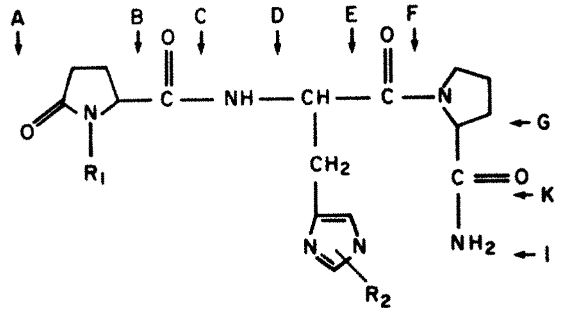
Table 2. CHARACTERISTICS OF PRINCIPAL IONS OBTAINED BY FRAGMENTATION OF OVINE TRF (METHYLATED DERIVATIVE) IN HIGH RESOLUTION MASS SPECTROSCOPY



Fragmentation points	Measured mass	Error mMU	Elemental composition
A→B	84·0463	+1·5	C_4H_6NO
A→B, $R_1 = CH_3$	98·0576	−3·0	C_5H_8NO
D→E	94·0535	+0·4	$C_5H_6N_2$
D→E, $R_2 = CH_3$	108·0673	−1·4	$C_6H_8N_2$
F→K, minus 4H	93·0211	−0·4	C_5H_3NO
F→I, minus 3H	110·0480	0·0	$C_5H_6N_2O$
G→I	44·0120	−1·6	CH_2NO
A→E, R_1 or $R_2 = CH_3$, minus H or C→K or D→I, minus H	234·1112	−0·4	$C_{11}H_{14}N_4O_2$
C→I, minus 2H	248·1147	0·0	$C_{11}H_{14}N_5O_2$
A→E, $R_1 = R_2 = CH_3$ or D→I, $R_2 = CH_3$ or C→K, $R_2 = CH_3$, minus H	249·1327	−2·4	$C_{12}H_{17}N_4O_2$

$R_1 = R_2 = H$, except when indicated otherwise in the table. Arrows and letters A–K indicate fragmentation points in mass spectroscopy. In non-derivatized ovine TRF, $R_1 = R_2 = H$.

Table 3. AMMONIA AND HISTIDINE CONTENTS IN 6 M HCl HYDROLYSATES OF ISOLATED OVINE TRF AND SYNTHETIC PEPTIDES

	No. of determinations	nmoles His	nmoles NH_3*	NH_3/His
Synthetic PCA-His-Pro-NH_2	6	38·4 ± 4·6†	40·3 ± 6·1	1·07
Synthetic PCA-His-Pro-OH	5	39·1 ± 3·3	0·4 ± 3·8	0·01
Ovine TRF	2	20·5 ± 2·1	22·1 ± 1·0	1·08
Ovine TRF unhydrolysed	1	—	−2·0	—

* Corrected for exogenous NH_3 in blank hydrolysed with each determination; average blank = 15·0 ± 5·7 nmoles NH_3 for seven determinations.

† Standard error.

activity of 44,000 ± 1,100 U/mg; the two figures for the respective specific activities are not statistically different. Natural ovine TRF as well as synthetic PCA-His-Pro-NH_2 are regularly active ($P \leq 0{\cdot}05$) in stimulating release of TSH *in vivo* (mouse TRF assay) in doses of 5 ng/animal, as a single intravenous injection; occasionally animals give a statistically significant response to a dose of 1 ng. Synthetic PCA-His-Pro-HN_2 stimulates release of TSH when administered orally to the assay animals in a dose of $\leq 1{\cdot}0$ μg (ref. 11). *In vitro*, hypothalamic ovine TRF or synthetic PCA-His-Pro-NH_2 stimulate release of TSH ($P \leq 0{\cdot}05$ in complete four-point assays with factorial analysis) at doses of ≥ 50 pg/ml. incubation fluid; this corresponds to about 1×10^{-10} mole TRF/ml./mg pituitary tissue. As is the case with natural TRF[12], pretreatment of the *in vitro* incubated pituitary with tri-iodotyronine (T_3) inhibits the response to the synthetic tripeptide amide (Table 4). The *in vivo* pituitary response as a function of time measured by plasma TSH concentrations, following intravenous injection of synthetic PCA-His-Pro-NH_2 (Table 5), is not statistically different from that observed for natural ovine TRF[13]. Pretreatment of the assay animals with a large dose of T_3 (0·25 μg) 2 h before injection of three different doses of synthetic tripeptide amide shows (Table 6) the same type of "competitive inhibition" as reported earlier for natural ovine TRF[14].

Table 4. BIOLOGICAL ACTIVITY OF PCA-His-Pro-NH_2 (X): *in vitro* RELEASE OF TSH; INHIBITION BY T_4

	mU TSH released/ pituitary/h	Potency ratio (95 per cent confidence limits)
C: Saline	1·1	
T: 5×10^{-11} g (X)/ml.	3·4	T/C = 2·5 (1·8–3·7)
C: Saline	0·8	
T: 5×10^{-10} g (X)/ml.	5·2	T/C = 7·2 (5·2–11·1)
C: 5×10^{-10} g (X)/ml.	5·1	
T: 5 μg T_4 pretreatment; 5×10^{-10} g (X)/ml.	2·8	T/C = 0·51 (0·35–0·72)

In vitro incubation of rat pituitary tissues as described in ref. 12; mU/TSH released/h calculated for all fluids in a single multiple four-point assay against TSH international standard. Potency ratio with confidence limits calculated by factorial analysis; see ref 23 for a complete mathematical description of these calculations for TSH/TRF assay. C, Control hemi-pituitaries; T, treated hemi-pituitaries.

Table 5. ACTIVITY OF PCA-His-Pro-NH_2 (X): ELEVATION OF PLASMA TSH IN NORMAL RATS

Treatment	Time (min)	μU TSH/ml. plasma (95 per cent confidence limits)	P
Saline	0	159 (82–248)	
Saline	+3	153 (76–243)	—
Saline	+10	115 (47–189)	—
Saline	+30	145 (71–226)	—
15×10^{-11} g (X)	0	131 (60–205)	
15×10^{-11} g (X)	+3	585 (360–1,570)	*
15×10^{-11} g (X)	+10	879 (500–3,170)	*
15×10^{-11} g (X)	+30	370 (238–736)	*

Plasma samples are aliquots from pools of six rats each receiving treatments as indicated, all animals anaesthetized with 'Nembutal' at time of injection (intrajugular); all injection volumes, 1·0 ml. *P*, Significance level by the multiple comparison test of Duncan; —, not different from control; * = 99 per cent; all calculations and statistical analyses as in ref. 23.

Table 6. ACTIVITY OF PCA-His-Pro-NH_2 (X): INTERACTION BETWEEN T_3 AND (X) ON THE RELEASE OF TSH *in vivo*

Treatment	N	TRF assay adj. $\log_{10}$ c.p.m. ± S.E.	P
Saline	3	3·1279 ± 0·0617	
5×10^{-12} g (X)	4	3·4657 ± 0·0534	*
2×10^{-11} g (X)	5	3·6132 ± 0·0493	*
8×10^{-11} g (X)	6	3·8218 ± 0·0437	*
T_3, saline	6	3·1244 ± 0·0436	
T_3, 5×10^{-12} g (X)	6	3·1065 ± 0·0437	—
T_3, 2×10^{-11} g (X)	7	3·1605 ± 0·0404	—
T_3, 8×10^{-11} g (X)	6	3·3022 ± 0·0437	—
T_3, 1×10^{-9} g (X)	6	3·4803 ± 0·0436	*

Experimental design and mathematical analysis as in ref. 14; *N* = number of assay animals/treatment; *P* as in Table 5; T_3: 0·25 μg intraperitoneal injection of tri-iodothyronine 2 h before TRF injection.

Synthetic PCA-His-Pro-NH_2, like natural ovine TRF[15], elicits a highly specific response in the release of TSH: PCA-His-Pro-NH_2 does not stimulate secretion of adrenocorticotropin or luteinizing hormone according to measurements performed concomitantly with TSH in the fluids of *in vitro* pituitary incubations; similarly, PCA-His-Pro-NH_2 does not stimulate secretion of luteinizing hormone *in vivo* in the rat (plasma levels measured by solid-phase radioimmunoassay) whereas it does stimulate secretion of TSH. Pure TRF has no oxytocic activity (rat uterus *in vitro*), no smooth muscle stimulating activity (guinea-pig ileum *in vitro*), no vasopressor activity (blood pressure recording of the pithed rat), no MSH activity (*in vitro* assay of Shizume *et al.*[16]). The biological activity of synthetic PCA-His-Pro-NH_2 is destroyed by incubation with plasma like that of hypothalamic ovine TRF (ref. 17 and W. V., R. B., T. F. D. and R. G., manuscript submitted). Furthermore, incubation of natural ovine TRF with a microbial pyrrolidone-carboxylyl peptidase (R. E. Fellows and A. Mudge, manuscript in preparation) destroys the biological activity; at the same time it liberates a ninhydrin-positive peptide which, as the free peptide or its dansyl-derivative, has chromatographic mobilities similar to those of a fragment—presumably His-Pro-NH_2—obtained by incubation of synthetic PCA-His-Pro-NH_2 in the same conditions. These results also favour the presence of an N-terminal PCA- in isolated ovine TRF. Plasma inactivation of TRF by a PCA-peptidase is an obvious possibility.

Conclusions in the Context of Other Work

Results from low and high resolution mass spectrometry, NMR and infrared spectrometry, thin-layer chromatographic data, amino-acid analyses and enzymatic degradation all favour the structure 2-pyrrolidone-5-carboxylyl-histidyl-proline amide (Fig. 6) for the ovine hypothalamic hormone TRF isolated in this laboratory. L-2-Pyrrolidone-5-carboxylyl-L-histidyl-L-proline amide prepared by synthesis has physical characteristics indistinguishable from those of natural ovine TRF; it also has similar biological activity.

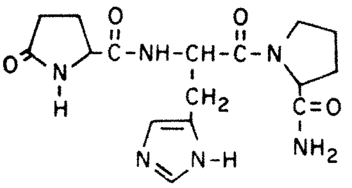


Fig. 6. Molecular structure of isolated hypothalamic ovine TRF.

Recently, Folkers *et al.*[18] and Bowers *et al.* (paper presented at a meeting of the American Thyroid Association, Chicago, November 1969) have confirmed that mixtures of synthetic peptides obtained by ammonolysis of the esterified derivatives of the sequence Glu-His-Pro have considerable TRF activity, in agreement with our earlier reports. Their statement that the synthetic peptides are not active orally is probably best explained by the fact that they administered doses of the materials which were too low. More recently, the same group[19] has reported on the similarity in properties of a preparation of porcine TRF[20] and a synthetic preparation "presumably (pyro)-Glu-His-Pro-NH_2" in a variety of thin-layer chromatographic systems and bioassays; characterization of the synthetic material was claimed on the basis of "its hydrolysis to the three amino-acids", its NMR spectrum and thin-layer chromatographic mobilities. Although other possibilities were considered, the authors concluded that the structure PCA-His-Pro-NH_2 was in agreement with the known properties of porcine TRF; these reports are reviewed in ref. 21. If the conclusions of Bøler *et al.*[19] are correct, then the structures of hypothalamic TRFs from two different species would be identical.

Our results, concerning the ovine TRF as it was isolated in our laboratory, do not exclude the possibility that the native molecule might exist as Gln-His-Pro-NH_2, the N-terminal glutamine having been cyclized to PCA-during the extraction procedure; there are precedents for this in the chemistry of the eledoisins[22]. The possible activity of synthetic Gln-His-Pro-NH_2 has not yet been studied.

For collaboration and advice we thank E. Horning, R. Stillwell, J. McCloskey, Institute for Lipid Research, Baylor College of Medicine, Houston; N. Chamberlain, M. Eastwood, Esso Research Center, Baytown, Texas; P. Bommer, Roche Laboratories, Nutley, New Jersey. M. Amoss and C. Rivier, Baylor College of Medicine, performed the radioimmunoassays for luteinizing hormone and adrenocorticotropin respectively. We thank D. Cedergren, J. Gaubatz, R. Givens, R. Pitcher, N. Pace, J. Randolph, S. Robinson and K. Wendler for technical assistance. This work was supported by grants from the US National Institutes of Health, the Population Council (to R. G.) and the Welch Foundation, Houston, Texas (to E. Horning).

Defective Viral Particles and Viral Disease Processes

by
ALICE S. HUANG

Massachusetts Institute of Technology,
Cambridge, Massachusetts 02139

Preparations of many different types of viruses contain defective particles which consist of viral structural proteins and a part of the viral genome. Such particles are capable of specifically interfering with the growth of homologous, standard virus and may play a major part in the evolution of viral diseases.

Biologically active defective viral particles have been described with increasing frequency in animal virus systems, suggesting that they may be more common than had been suspected. We propose that such defective particles have a role in determining the evolution of viral diseases. Many host defence mechanisms are known which combat viral infections[1,2]. These involve antiviral antibodies and lack of attachment sites on host cells. General factors such as fever, localized acidity, heredity and interferon have also been implicated but, except for some tentative suggestions[3-5], the defective virus has been overlooked as a possible important determinant in the outcome of natural viral infections.

To support our hypothesis that defective viral particles play a part in the course of viral infections, the present knowledge of defective particles will be summarized. Some *in vitro* studies will be presented which relate to known disease processes, and an explanation at the molecular level will be offered for the appearance of defective particles in viral preparations and for the biological activity of defective particles.

The defective particles which are pertinent here have the following properties: (1) they contain normal viral structural protein; (2) they contain a part of the viral genome; (3) they can reproduce in the presence of helper virus; (4) they interfere specifically with the intracellular replication of non-defective homologous virus. When defective particles are added to infected cells, the yield of non-defective virus is reduced. This interference can occur in the absence of detectable interferon and is dependent on the nucleic acid contained in defective particles. As will be seen, this specific interference by defective particles may be an important mechanism in virus–host interactions.

Because defective virus with the properties mentioned above occur in many and possibly all animal virus systems, we propose to call them DI particles (DI = defective interfering). The non-defective homologous virions which are capable of independent replication are called standard virus.

Animal Viruses which form DI Particles

Von Magnus[6] first described "incomplete" or DI particles, produced after inoculation of fertilized eggs with high multiplicities of influenza virus. The DI particles are antigenically identical to standard virions[7,8] but are lacking the largest of the RNA species found in standard virions and contain small, unidentified pieces of RNA[9].

The synthesis of similar DI particles by cells or animal tissues on infection with high multiplicities or "undiluted passage virus" has now been reported for Rift Valley fever virus[10], vesicular stomatitis virus[11], fowl plague virus[12], simian virus 40 (ref. 13), polyoma virus[14], lymphocytic choriomeningitis virus[15], Sendai virus[16], simian virus 5 (personal communication from P. W. Choppin), and poliovirus (unpublished observations). Of these viruses, vesicular stomatitis DI particles are the best characterized in respect of biological and physical properties because they differ in length and are readily separated by rate zonal centrifugation[17-22].

Defective Particles in Viral Disease: A Model

From our studies on vesicular stomatitis virus and from the published data on influenza, we have composed a diagrammatic representation of the virus–host interaction in conditions where DI particles are produced (Fig. 1). Initially, one standard particle infects a cell and produces more standard virions which then infect other cells. Very occasionally, a DI particle arises in a cell infected with standard virions. Once the DI particle appears in a viral preparation, it begins to replicate together with standard virions and eventually DI particles are the predominant component in the viral progeny. As more DI particles are produced, less standard virions are present. Because their ability to replicate is dependent on standard virions, the concentration of DI particles will decline as the infection spreads until a few DI and standard virions are left. At this stage specific antibodies or other factors can neutralize the remaining virions. This course of events, as depicted in result II, Fig. 1, may represent acute self-limiting viral disease.

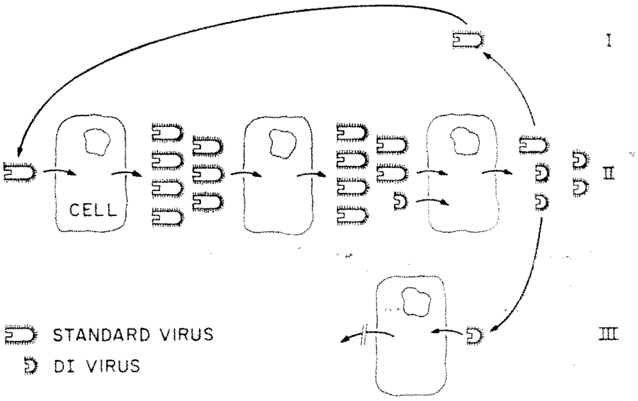

Fig. 1. A model for the role of DI particles in the course of viral infections.

In the absence of antibodies and in the presence of only a few viral particles, cells will be infected by only single DI or standard virions. Cells infected with only standard virions will produce a new crop of standard virions (result I, Fig. 1) while cells infected with only DI particles will produce no yield (result III, Fig. 1). The consequence will be an overall increase of standard virions and a new cycle of infection. Repeating cycles of infection could continue indefinitely, producing recurrent bouts of acute illness or viraemia, but synthesis of standard and DI particles may be in such balance that only a very few virions are synthesized and the infection would remain in a subacute or latent form until the balance is upset.

Because the model system seems to fit descriptions of viral disease processes, let us look at some of the data on viral infections to see if there is support for the existence of DI particles during natural infections.

Acute and Persistent Infections

Although many viruses known to cause acute illnesses produce DI particles in laboratory conditions, DI particles have not been isolated from naturally occurring infections in animals. Nevertheless they are not artefacts of cells in tissue culture. They are produced in mouse brains[10] and in chick embryos[6,16,23]. The ability of DI particles to prolong survival has been documented for influenza virus[24] and Rift Valley fever virus[10]. The present understanding of DI particles enables us now to study them in relation to the evolution of acute viral diseases.

One of the best studied persistent viral diseases is lymphocytic choriomeningitis (LCM). In adult mice, infection with LCM virus is fatal, but young mice become immunologically tolerant, and the virus persists throughout their lifetime[25,26]. Interferon is not found in the infected animal nor does LCM virus induce the synthesis of interferon in cell cultures[27]. Lehmann-Grube *et al.*[15] established a persistent culture of L-cells by inoculating them with a high multiplicity of LCM virus. Only DI particles were produced and the cells exhibited intracellular interference with superinfecting standard virus, suggesting that the DI particle and its specific interference might maintain the persistent infection in adult, tolerant mice.

Defective particles of measles virus[28] may be an interfering agent in conditions where few standard particles are recovered and large amounts of viral nucleoprotein tubules remain associated with infected cells[29,30]. The situation seems to be similar to that in cells infected with fowl plague virus, in which, in conditions of interference by DI particles, viral ribonucleoprotein accumulates in the cells[12]. Measles virus has long been suspected of being related to the causative agent of a disease of the central nervous system known as subacute sclerosing panencephalitis (SSPE). Recent isolations of the virus from a brain biopsy suggest that measles virus can persist in its host and cause the disease of SSPE[31-33]. This may be the result of interference by DI particles, accounting for the slow progression of the disease, as well as for the difficulties encountered in isolating standard measles virus from infected brain tissue.

Besides interfering with the growth of standard virus, DI particles often have other properties which are consistent with their content of viral structural proteins and part of the viral genome. For example, vesicular stomatitis DI particles inhibit host RNA synthesis[34], fowl plague DI particles produce fluorescent antigen[12], and DI particles of simian virus 40 produce T antigen[35]. Thus, depending on the particular virus system, DI particles may show a variety of particle–host interactions in the absence of standard virions.

Control by the Host Cell

A number of factors seem to affect the synthesis of DI particles but none have been studied extensively. Some *in vitro* experiments show that the species of host cell greatly affects synthesis of DI particles. Madin-Darby bovine kidney cells can be infected at high multiplicities with influenza virus without marked interference, whereas chick cells of the chorioallantoic membrane readily produce influenza DI particles[23]. When vesicular stomatitis virus is grown in identical medium and culture conditions, but in two different cell lines, the bovine kidney cells or Chinese hamster ovary cells, different ratios of the two types of virus particles are made depending on the species of host cells. Table 1 shows the production of standard VSV particles after successive undiluted passages. Interference readily occurs in Chinese hamster ovary cells where two successive undiluted passages reduce the standard virus to 0·1 per cent of the original titre. Moreover, the harvest of DI particles of VSV is highest after the first undiluted passage; successive passages also result in reduced synthesis of DI particles[36]. By contrast, Madin-Darby bovine kidney cells produce standard VSV at about 10 per cent of the original titre through five successive undiluted passages.

These results suggest that host cells exert control over the synthesis of DI particles. The permissiveness of certain cells or tissues to production of DI particles may account for the localization of certain viral diseases as well as for the variation in virulence of a given virus in different hosts.

It is noteworthy that by the fourth successive undiluted passage of VSV in Chinese hamster ovary cells, standard virus undergoes a burst of synthesis as predicted by the model (result II, Fig. 1). Such cyclic activity has also been observed in a cell culture persistently infected by another plaque variant of VSV, although the production of DI particles was not measured[37]. Even with one of the most virulent viruses, therefore, persistently infected cell cultures can be maintained in the absence of antibody or significant amounts of interferon.

Table 1

Undiluted passage*	Plaque forming units per ml. Chinese hamster ovary cells	Plaque forming units per ml. Madin-Darby bovine kidney cells
1	$7{\cdot}55 \times 10^8$	$4{\cdot}68 \times 10^8$
2	$3{\cdot}02 \times 10^6$	$1{\cdot}25 \times 10^8$
3	$4{\cdot}40 \times 10^4$	$1{\cdot}00 \times 10^8$
4	$3{\cdot}38 \times 10^7$	$3{\cdot}95 \times 10^8$
5	—	$4{\cdot}60 \times 10^8$

* A VSV (large plaque, Indiana serotype) preparation at 2×10^9 plaque forming units/ml. was used at an input multiplicity of 100 to infect either Chinese hamster ovary or Madin-Darby bovine kidney cells (a gift from Dr P. W. Choppin) grown to confluence in a 100 mm Falcon plastic Petri plate in Joklik's modified minimal essential medium (Grand Island Biological) with added non-essential amino-acids and 7 per cent foetal calf serum. After incubation at 37° C in a 5 per cent CO_2, humidified incubator for 16–18 h, the medium was collected. Successive undiluted passages were made by infecting similar cell monolayers with 0·5 ml. of the previous yield followed by the same conditions of incubation. Standard VSV grown in Chinese hamster ovary or Madin-Darby bovine kidney cells were assayed for plaque formation on Chinese hamster ovary monolayers as described previously[38].

The age of the animal and temperature of incubation may also affect the production of DI particles. Experiments with chick embryos show that VSV grows better at 34° C than at 39° C (ref. 38) and that 7 day old embryos support the growth of standard VSV better than 10 day old embryos. Although DI particles were unknown at the time of these studies, they may have played a part in the prolonged survival of chick embryos infected with VSV and incubated at the higher temperature.

Many other factors, such as conditions prevailing in the inflammatory zone, heredity, and hormonal agents may also affect synthesis of DI particles. Undoubtedly, observations concerning DI particles will become more common as the large number of factors influencing their production become understood.

The Mechanism of Interference

Production of DI particles is a two step process. The first is the initial formation of a single DI particle from a preparation containing only standard virus. The second is the replication of the DI particle at the expense of standard virus and its ultimate domination of the virus yield. The latter stage represents the phenomenon of interference.

Because DI particles arise from clonally purified standard particles[14,35,39,40], the first stage must be the initial synthesis of a small piece of nucleic acid capable of combining with viral structural proteins to form a defective particle. The frequency of formation and the size of such a small piece of nucleic acid must necessarily depend on the mechanism of nucleic acid replication of the different viruses and might be viewed as the production of a deletion mutant. For instance, influenza virus which has its genome in several small pieces forms DI particles with greater frequency than poliovirus which contains a single piece of RNA. Also, viruses which normally synthesize smaller pieces of nucleic acid for purposes other than incorporation into progeny virions might be expected to have a relatively high frequency of formation of DI particles. An understanding of the replication of nucleic acids of different viruses, therefore, would shed light on the frequencies of occurrence of DI particles for different viruses as well as for different strains of the same virus. Whether the initial appearance of DI particles is also dependent on a host cell factor is at present unknown.

Interference is usually detected when cells are infected with high multiplicities of unpurified virus or when purified DI particles are added to cells infected at low multiplicities with standard virus. These conditions favour the co-infection of cells by DI and standard virions. With VSV in tissue culture cells, complete interference is correlated with cessation of all viral RNA synthesis; whereas, during partial interference, there seems to be a competition between the synthesis of small RNA and large RNA[36]. Interference by DI particles may be analogous to a phenomenon which occurs during the *in vitro* synthesis of bacteriophage Qβ RNA. Small Qβ RNA fragments compete successfully with the large complete Qβ RNA for replicase and ultimately dominate the reaction (ref. 41 and personal communication from L. E. Orgel).

We conclude that DI particles may be important determinants of the course of acute, self-limiting viral infections and of persistent, slowly progressing viral diseases. In addition, many host reactions may alter the production of DI particles and thus influence the outcome of viral infections. The test of these ideas lies in future experiments on the details of the course of viral infections.

We thank Dr Andre Lwoff for his critical evaluation of the manuscript, and Dr Purnell W. Choppin for making available unpublished data and for helpful discussions. The work was supported by grants from the American Cancer Society and the US National Institute of Allergy and Infectious Diseases. D. B. received a faculty research award from the American Cancer Society.

Magnetic Anomalies and Seafloor Spreading Rates in the Northern South Atlantic

by

TJ. H. VAN ANDEL

Oregon State University,
Corvallis, Oregon 97331

A geomagnetic profile across the northern South Atlantic yields spreading rates for the last 70 m.y. which vary from 1·6 to 2·0 cm/year. There is evidence for three regional discontinuities in the spreading history of the South Atlantic.

FOLLOWING the development of the Vine–Matthews hypothesis of seafloor spreading[1], spreading rates have been determined for the North Atlantic between the Reykjanes Ridge and 11° N latitude[2,3] and for the extreme southern Atlantic[4]. These rates enabled LePichon[5] to demonstrate that the American and European–African blocks rotated around a pole located, during the latest phase, near south-eastern Greenland. Supporting data from the northern South Atlantic have so far been lacking.

On the CIRCE Expedition of the Scripps Institution of Oceanography in November 1968, we obtained a geomagnetic profile from Luanda, Angola, to Fortaleza, Brazil (Fig. 1). The total field magnetic readings were digitized and the International Geomagnetic Reference Field was removed by computer[6]. In the centre of the ocean, the anomalies are predominantly negative with respect to the reference field; near the Brazilian and African continental margins, they become positive. The profile crosses the east flank of the mid-Atlantic Ridge between 7° and 8° S latitude, approximately perpendicular to the ridge axis. Just beyond anomaly 4 on the west flank, it is interrupted by a northward leg crossing the Ascension fracture zone, and the principal west flank crossing starts to the west of the axis in the block north of the fracture zone. Here, the track veers approximately 70° W of the ridge axis.

The profile is relatively close to the magnetic equator, which lies approximately 20° N. Nevertheless, by comparison with North and South Pacific standard profiles, and profiles published for the South Atlantic[4], many anomalies could be identified with a reasonable degree of certainty, especially numbers 5, 6, 12, 13, 18, 20 and 21 (Fig. 1). The identity of intermediate anomalies was then established. On the east flank, anomalies up to 32 could be recognized; on the west flank, the pattern extends out to anomaly 30. Detailed surveys in four locations on the east flank confirm that the anomalies veer slightly west of north, and that offsets do not exceed 10 km, thus providing a confidence limit for the distance estimates. There is no evidence that fracture zones other than the Ascension fracture zone were encountered.

Ages for the numbered anomalies have been proposed by Heirtzler *et al.*[7]. Recent data from the Atlantic operations of the drilling vessel Glomar Challenger[8] agree with this time scale.

A plot of the assumed ages of the east and west flank anomalies against distance from the ridge axis is given in Fig. 2. For the west flank, the distances were corrected by projecting the anomaly peaks on a line perpendicular to the ridge axis; for the east flank, such a correction is not necessary. Anomalies 1–4 of the west flank are on a direct extension of the east flank profile; for anomaly 6

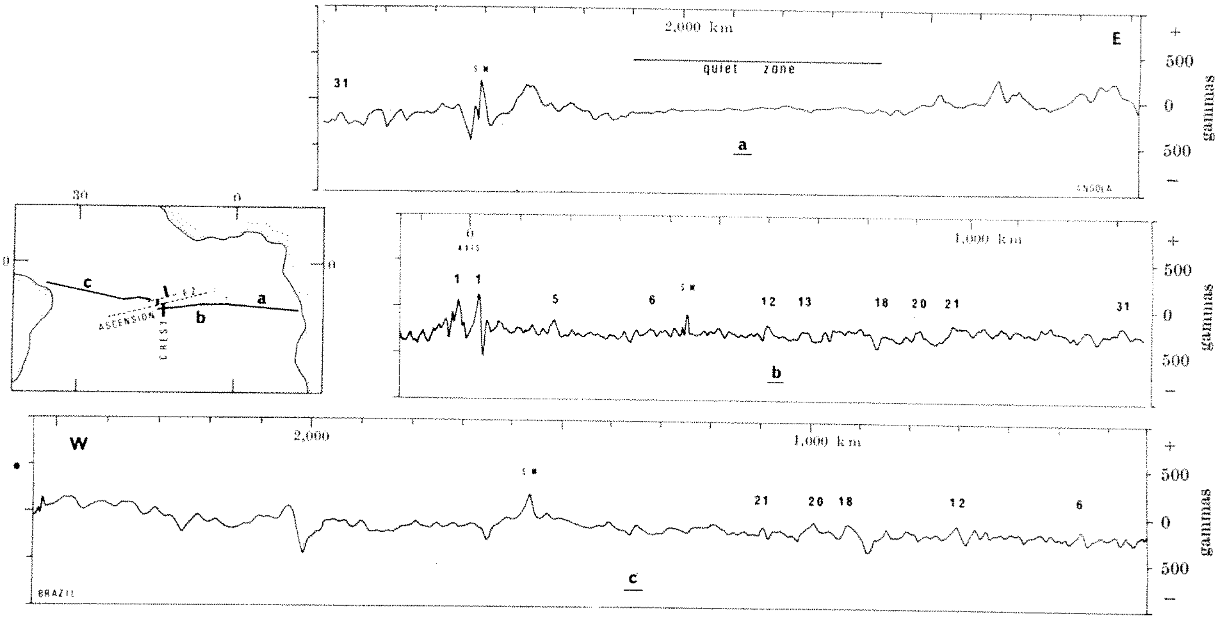

Fig. 1. Geomagnetic anomalies in the northern South Atlantic along CIRCE track shown in inset. Numbered anomalies correspond to classification of Heirtzler *et al.*[7]. For details of correlation, compare Figs. 3, 4 and 5 in Dickson *et al.*[4]. Sea-mounts affecting anomaly pattern are labelled SM.

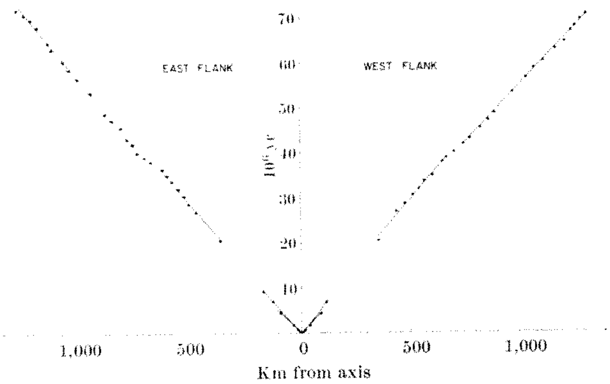

Fig. 2. Distance from ridge axis of numbered anomalies on CIRCE profile plotted against time scale of Heirtzler *et al.*[7]. Axial position for anomaly 6 and beyond on west flank determined by extrapolation backward, using spreading rate for anomalies 1–4. Distances for west flank projected on line perpendicular to ridge axis. Regression lines fitted by least squares (see Table 1).

and beyond, located in the block north of the Ascension fracture zone, the position of the axis was determined by extrapolation from anomaly 6, using the spreading rate obtained from anomaly 1–4. The position of the axis so obtained is in accordance with earthquake epicentre locations[10], and shows a left lateral offset of approximately 80 km across the Ascension fracture zone.

On each flank, the points fall close to several straight line segments. The least squares fit of the regression lines shows very high correlation coefficients, small standard errors for the spreading rates, and high levels of significance for most differences between spreading rates—both for successive line segments and for opposite pairs on east and west flanks (Table 1). The rates for the most recent phase of spreading are in good agreement with the pole of rotation postulated by LePichon[5].

Table 1. SPREADING RATES IN THE SOUTH ATLANTIC OCEAN BETWEEN 6° AND 8° S LATITUDE

Anomaly number	n	r	West flank spreading rate	Standard error	n	r	East flank spreading rate	Standard error
0– 3	4	0·99	1·89 cm/yr	0·04	4	0·99	2·16 cm/yr	0·24
0– 5	5	0·99	1·60	0·14	6	0·99	1·82	0·10
7–12	6	0·99	1·80	0·06	6	0·99	1·78	0·06
14–32	17	0·99	1·98	0·02	18	0·99	1·70	0·02

n : number of anomalies in series.
r : least squares correlation coefficient.

Spreading rate differences between successive series on each flank and between opposite series on east and west flank are significant at the 95 per cent level or better (t test), except for the 0–5 and 7–12 series on the east flank which are significantly different only at the 90 per cent level, and 7–12 series on east and west flank which are not significantly different at the 75 per cent level.

Spreading rates between the axis and anomaly 3 are approximately 2 cm/yr with the east side spreading slightly, but significantly, faster. Between anomalies 3 and 4 there is a discontinuity. A discontinuity at this point has also been observed in the North Atlantic[2,3,11,12] and the North Pacific[1]. Another discontinuity between anomalies 5 and 7 is characterized on the east flank by an offset and a change in spreading rate. On the west flank, this discontinuity is not well established: the wide spacing of anomalies in this interval, the absence of anomaly 5, and the break in the record render the data for this section inconclusive. Ewing and Ewing, and Schneider and Vogt[13,14], have argued that there was a major discontinuity approximately 10 m.y. ago, either as a period of quiescence or as a marked reduction of the spreading rate, and LePichon[5] has included it in his reconstruction of the spreading history of the Atlantic. Our data modestly support these interpretations.

Between anomalies 7 and 12, a uniform spreading rate is obtained on both sides of the crest, followed by a brief but clear discontinuity approximately 35–38 m.y. ago. This discontinuity is marked by a temporary sharp decrease in the spreading rate. As far as we are aware, it has not been reported from elsewhere. It is followed by another and prolonged period of uniform spreading extending to the last observed anomalies. During this period, the spreading rate on the east flank is significantly lower than the rate on the west flank. The opposite would be expected because, according to LePichon's reconstruction for this period, the east flank here is at a greater distance from the rotational pole than the west flank. LePichon also showed that a considerable reorientation of the spreading direction has occurred for this phase. Projection of the CIRCE spreading rates on appropriate perpendiculars to the axis only increases the asymmetry. This asymmetry in spreading rate could account for the asymmetry of the Atlantic basin at this latitude. The rates are in reasonable agreement with the regional rate postulated by LePichon for the situation prevailing at the time of anomaly 31.

To compare the breaks observed in our profiles with other data from the South Atlantic, we have plotted the anomalies of Dickson *et al.*[4] against their assumed ages (Fig. 3), together with the CIRCE data. The profiles show, without exception, the discontinuity near anomaly 3, and in all cases except *V*-22 (where the upper bound is not clear), also the break near anomaly 6. The break between anomalies 12 and 13 or 14 is also well defined except in *C*-8. The data have been taken from figures in Dickson *et al.*[4] and are not highly accurate; nevertheless, the possible error of 10–20 km does not seriously affect the trends.

Fig. 3 shows that, relative to an arbitrary time scale, there have been several distinct and widespread discontinuities in the spreading history of the southern mid-Atlantic ridge. In the plate tectonic concept[5], such discontinuities can be explained either by an overall change

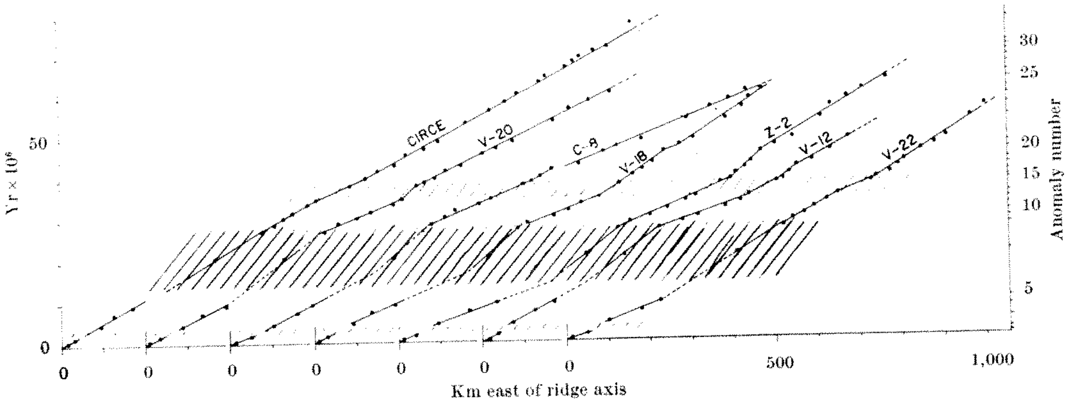

Fig. 3. Distances to ridge axis of numbered anomalies on east flank of mid-Atlantic ridge in the Southern Atlantic Ocean, plotted against geomagnetic time scale of Heirtzler *et al.*[7]. Data from Dickson *et al.*[4]. Shaded zones indicate regional discontinuities.

in the rate of production of new crust, or by a shift in the pole of rotation of the plates. A regional map of the anomalies would reveal a change in the pole of rotation as a reorientation of the trends of the anomalies. A change in spreading rate can only be established by reference to an absolute time scale calibrated by radiometrically or palaeontologically dated samples. Such a time scale may soon be possible.

The east flank profile shows several additional anomalies above 32, although the record here is disturbed by the presence of two sea-mounts. Beyond that area, there is a magnetically quiet zone, 400 km wide. Extrapolation of spreading rates suggests that the western edge of this quiet zone is about 100 m.y. old. On the west flank, no quiet zone is found; pronounced anomalies continue to the margin of the continent. Heirtzler and Hayes[15] described quiet magnetic zones flanking the mid-Atlantic ridge in the North Atlantic and they have suggested that these are produced by continued spreading during a period devoid of magnetic reversals. Drake and others[16], on the other hand, considered the quiet zones of the North Atlantic to be part of the floor of a proto-Atlantic Ocean which predates the onset of the current period of continental drift.

The absence of a quiet zone on the west flank of the CIRCE profile argues against the assumption that it is caused either by the process postulated by Heirtzler or by the effect of the low magnetic latitude. Drake's hypothesis is obviously attractive, but because the fit of the South Atlantic margins is excellent, new difficulties would arise from fitting the Brazilian margin against the westward limit of the quiet zone in the eastern basin. Dickson *et al.*[4] have noted the presence of a quiet zone in the Rio Grande basin, and show anomaly profiles with a quiet zone in the Cape basin, but there are insufficient data as yet to evaluate its regional distribution. The absence of a quiet zone in the western part of the northern South Atlantic indicates a very asymmetric distribution of spreading rates for the earliest spreading phase.

This investigation was supported by contracts of the US Office of Naval Research with Scripps Institution and Oregon State University, and by grants of the US National Science Foundation. We thank D. F. Heinrichs and M. Gemperle for their assistance and advice.

How Thick is the Lithosphere?

by
H. KANAMORI*
FRANK PRESS
Department of Earth and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts

A rapid decrease in shear velocity in the suboceanic mantle is used to infer the thickness of the lithosphere. It is proposed that new and highly precise group velocity data constrain the solutions and imply a thickness near 70 km.

THE hypotheses of seafloor spreading and plate tectonics have received much attention lately because they explain in a consistent manner the pattern of magnetic anomalies on the seafloor, the distribution of earthquake belts and the thickness and ages of deep-sea sediments. According to these hypotheses the lithosphere (composed of the crust and the rigid cap of the upper mantle) is divided into a number of rigid plates in constant motion. The plates are created along midocean ridges and are destroyed in the process of sinking back into the mantle in the vicinity of deep-sea trenches. The lithosphere is underlain by the asthenosphere—a weak zone coincident with the seismic low velocity layer, and probably the source region of basaltic magma.

This article is concerned with the problem of determining the thickness of the suboceanic lithosphere. Thickness is an important parameter which enters discussions of the mechanism of plate tectonics and the thermal regime in the lithosphere.

The thickness of the lithosphere may be estimated in several different ways. For example, seismic focal depths under Hawaii presumably are coincident with the zone at the base of the lithosphere where magma enters the fissure system which ultimately leads to the surface. A value of 60 km was found[1]. Seismic focal depths at midocean ridges extend to 65 km, this limiting depth presumably marking the base of the lithosphere[2]. The most direct indication of the thickness of the lithosphere is the shear velocity distribution with depth. A reversal in shear velocity in the suboceanic mantle now seems to be uniquely established although the details of the velocity–depth curve are still uncertain. Presumably the high velocity lid to the low velocity zone coincides with the lithosphere and the base of the lithosphere is marked by a rapid decrease in shear velocity. This method has been used by several investigators and values ranging from 40 to 70 km have been reported. Unfortunately these determinations are subject to the well known lack of uniqueness of surface wave methods, especially when density and shear velocity are both allowed to vary.

In this article we use new and highly precise group velocity data to test models found by F. P. using a Monte Carlo procedure and reported in an earlier paper[3]. In the previous work randomly selected models were required to fit Love and Rayleigh wave phase velocities pertinent to oceanic paths, eigenperiod data, mass and moment of inertia of the Earth. In the new test, group velocities are calculated for each model and compared with the new group velocity values of H. K.[4] which are based on thirty sets of data for predominantly oceanic paths. These are more data than previously available, leading to good estimates of the errors. This is a stringent test because group velocity is associated with the derivative of phase velocity with respect to period and a slight difference in slope of phase velocity shows up more clearly in the group velocity curve.

---

* On leave from Earthquake Research Institute, Tokyo University.

The results for Rayleigh waves are shown in Fig. 1. H. K.'s experimental group velocities together with error indications ($\pm\sigma$) are shown with group velocities calculated for various models. Also shown are the early data of Ewing and F. P.[5]. The Haddon–Bullen model HBI (ref. 6) fails to fit the data between 150 and 200 s. The Gutenberg–Bullen A model (ref. 7) fits the data somewhat better, but this model must be rejected because of its failure to fit the Love wave observations (not shown here). The well known models **8099** (ref. 8) and CIT 11A (ref. 9) do not fit the new Rayleigh wave group velocity data. All twenty-eight models of F. P. fit the Love wave group velocities but only seven fit the Rayleigh wave data within $\pm 2\sigma$. Two of these are shown in Fig. 1 (5·08, 9·71) together with two models which fail (6·21, 7·77).

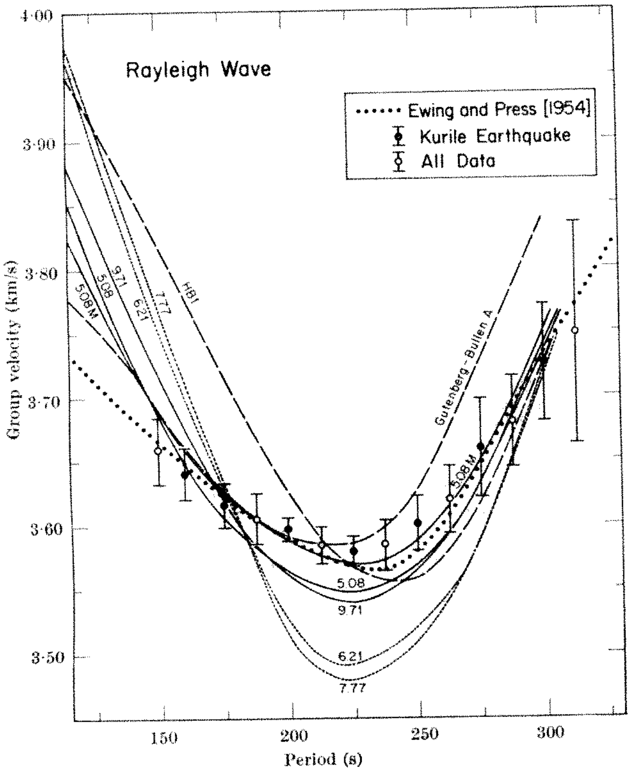

Fig. 1. Rayleigh wave group velocity data compared with several theoretical models; vertical bars indicate $\pm\sigma$.

The seven successful models are illustrated in Fig. 2. All show a large decrease in shear velocity beginning at 70 km. In the absence of an analytical method for establishing uniqueness with the data used, we interpret the narrow envelope formed by the models between 70 and 145 km as strong evidence that the data highly constrain the solutions. Numerical experiments were made in which the models were varied over smaller steps than with the Monte Carlo solutions. What seems to be required to find solutions which fit the group velocity data to $\pm 1\sigma$ is an almost abrupt velocity drop at a depth of 70 km as shown by model 5·08 M in Fig. 3. The fit of this model to the data is shown in Fig. 1. From these results we conclude that the base of the lithosphere is at a depth not much different from 70 km.

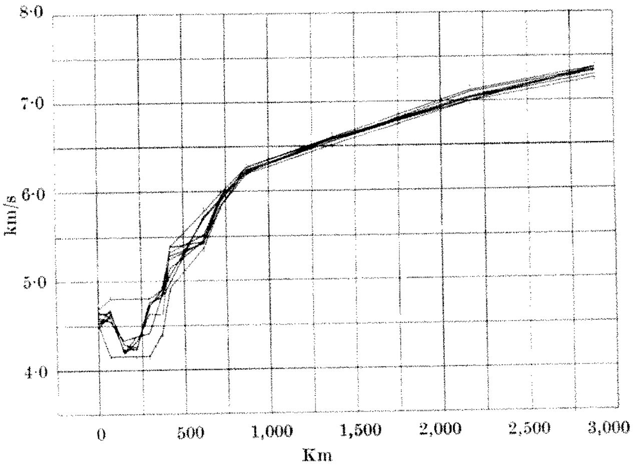

Fig. 2. Shear velocity distributions in the Earth's mantle which fit new group velocity data.

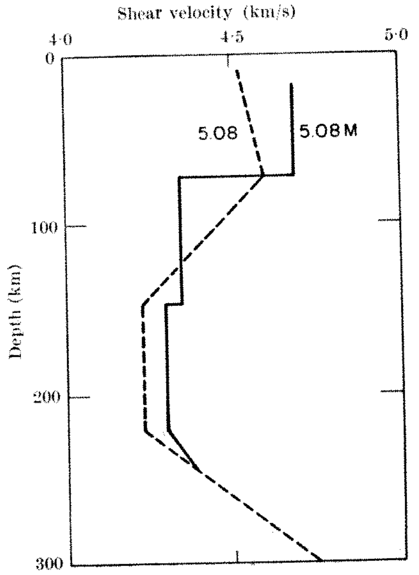

Fig. 3. Modification of model 5·08 to 5·08 M to obtain better fit to group velocity data.

Although several previous investigators (see ref. 10, for example) found similar results, we believe that our procedures remove the uncertainties which accompany surface wave studies. This is based on the agreement between models in which density and shear velocity were randomly selected and subjected to tests against data of known precision.

The sharp decrease in rigidity near 70 km supports the notion that the lower boundary of the lithosphere is determined by the solidus.

This study was supported by the Advanced Research Projects Agency and monitored by the US Air Force Office of Scientific Research.

Linear Polarization of Distant Quasars

MEASUREMENTS of the linear polarization of quasars at a wavelength of 49 cm (m_{49}) have already shown that this parameter is correlated with spectral index α (ref. 1). We have now observed a more complete sample of 93 quasars, all of which have measured redshifts. The correlation between m_{49} and α is confirmed, but a further correlation has been detected, namely between m_{49} and redshift z. The relation between m_{49} and z is shown in Fig. 1. The redshifts are taken from Burbidge and Burbidge[2], Schmidt[3] and Hiltner *et al.*[4]. The spectral indices represent the spectral slope at or near 49 cm. The separation between flat spectrum and steep spectrum quasars is especially marked for low redshifts ($z < 1{\cdot}25$). This separation does not exist for polarization measured at shorter wavelengths, and is therefore a depolarization effect, presumably by Faraday rotation within the source. Fig. 1 shows that the median value of m_{49} falls markedly as z increases for flat spectrum quasars. The median value of m_{49} is almost independent of z for steep spectrum quasars.

Both these trends with z are at variance with what one might expect on simple arguments. Measurements at a given observed wavelength correspond to emission at an emitted wavelength λ_{em} which progressively decreases with increasing z. For example, our observations correspond to $\lambda_{em} = 21$ cm for $z = 1{\cdot}3$ and $\lambda_{em} = 14$ cm for $z = 2{\cdot}5$. Because, on average, sources show an increase of polarization with decreasing wavelength, one would expect an increase in median m_{49} with z. This argument applies whether or not the redshift z is cosmological in nature.

Linear polarization has been measured in the wavelength range 6–21 cm (refs. 5–9) for 40 out of the 68 quasars with $z < 1{\cdot}25$. We have used these data to estimate the median polarization as a function of emitted wavelength, from which we may deduce the expected polarization as a function of observed wavelength for quasars of high z. The dashed lines in Fig. 1 show the results of this analysis, and indicate that quasars of both spectral types show less polarization at λ49 cm than expected. In each case the reduction is by a factor of about three.

A similar analysis for a shorter observed wavelength (λ18 cm) shows no effect, so the reduction we observe is not a difference of intrinsic polarization, but must be due to a depolarizing mechanism. In view of the similarity in reduction factor for steep spectrum and flat spectrum quasars, the depolarization is unlikely to be due to dilution by unpolarized components with abnormal spectra.

Faraday depolarization in the Milky Way does not produce a significant effect as the sources all lie at galactic latitudes $> 10°$. The effect of other, intervening, galaxies has been discussed by Wagoner[10] and others[11]. The probability that a galaxy lies on the line of sight to a quasar at $z = 2$ is about 10 per cent, depending on the size and space density of galaxies out to this distance. The depolarization we observe might be produced by Faraday rotation in randomly distributed objects, but only if their size or space density beyond $z = 1$ exceeds the local value for galaxies.

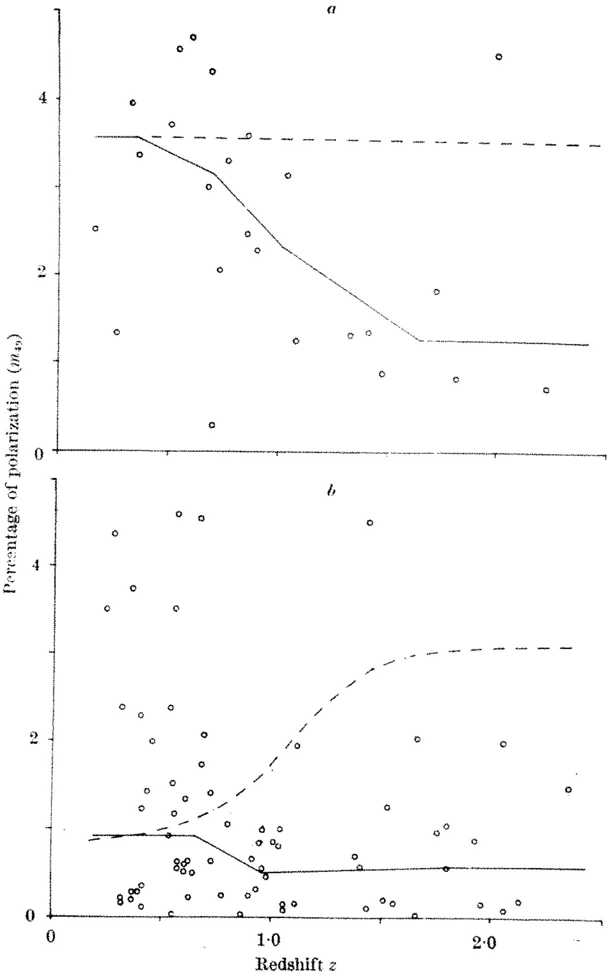

Fig. 1. The polarization (m_{49}) of (*a*) flat ($\alpha > -0{\cdot}5$) and (*b*) steep spectrum ($\alpha < -0{\cdot}5$) quasars. The solid lines represent the median lines. The dashed lines show the expected trends (see text).

Whether the intervening objects are randomly distributed, or are physically associated with the sources, they should show other absorption effects. Table 1 compares the linear polarization of high redshift quasars with and without redshifted absorption lines[2]. Those with absorption lines show significant depolarization compared with the remainder. Though the size of the sample is small, we believe that the depolarization is due to Faraday rotation in the same regions as are responsible for the absorption lines.

Table 1. QUASARS WITH REDSHIFT $z > 1{\cdot}25$

	Number	$\overline{m}_{49}$
Absorption lines	7	$0{\cdot}56 \pm 0{\cdot}21$
No absorption	18	$1{\cdot}38 \pm 0{\cdot}29$
Difference		$0{\cdot}82 \pm 0{\cdot}36$

Faraday depolarization requires that the rotation in the intervening cloud shall be at least 2 rad at the wavelength concerned. For $Z_{abs} = 2$ this wavelength is 16 cm, and hence the necessary rotation measure is ≥ 80 rad m^{-2}. The integral $\int N_e . B_{\|} . dl$ to achieve such a rotation measure is 10^{-4} cm^{-3} G pc. For comparison, a line of sight passing through a spiral galaxy suffers a rotation measure of about 30 rad m^{-2}.

This information from the Faraday rotation should be of great importance in helping to define the nature of the objects responsible for the absorption lines.

Upper Limit on the Intensity of Sgr γ-1 in Soft X-rays

FRYE *et al.*[1] have reported evidence for a point source of γ-rays, Sgr γ-1, with an intensity $I_{\mathrm{Sgr}\,\gamma-1}(>50\ \mathrm{MeV}) = (3 \pm 1) \times 10^{-5}$ photons cm^{-2} s^{-1}. It was seen in two separate balloon flights in February 1969 at a significance level of about three standard deviations of the background rate. Frye *et al.* give the coordinates of the source as right ascension = 19 h 12 m ± 12 m and declination = $-35° \pm 2°$.

It is important to have confirmation of the existence of the source Sgr γ-1. Assuming the source is real, however, we can set an upper limit on its intensity in soft X-rays (1·5–6 keV) from an Aerobee rocket experiment flown on July 7, 1967, by Bradt *et al.*[2]. Two banks of proportional counters, with 50 μm beryllium windows, each of area 350 cm^2, were collimated to 2·1° × 20° (FWHM). The long directions of the fields of view crossed one another at 60° and the centre of the field of view moved along a path of almost constant declination of $-24°$ from right ascension 21 h 06 m to 18 h 12 m at a fast roll rate of 3·5° s^{-1}. Subsequently the detectors scanned the Sagittarius sources, Sco X-1 and M-87, at a slow roll rate of 0·3° s^{-1}. During the fast roll each bank of counters looked at the Sgr γ-1 source for 1·4 s. The altitude of the rocket varied between 109 and 120 km during the fast roll. The counting rate in the 1·5–6 keV energy region in each bank remained stable at 55 counts s^{-1} or ~0·16 counts cm^{-2} s^{-1} during the entire fast scan. No source with a peak rate exceeding three standard deviations of the background rate (40 counts s^{-1}) was observed in the fast scan[2]. This corresponds to a threshold source intensity of ~0·12 counts cm^{-2} s^{-1} for a source at the centre of the field of view.

The effective area of each bank of detectors while transiting Sgr γ-1 depends on the declination of the source. It is 20, 38 and 45 per cent of the area (350 cm^2) for declinations $-37°$, $-35°$ and $-33°$ respectively. Taking into consideration the error in declination ($-35° \pm 2°$) given for the source, we take 20 per cent of 350 cm^2 as the minimum effective area. Combining the data of both banks of detectors we can set an upper limit to the strength of Sgr γ-1 in the 1·5–6 keV region as 0·4 counts cm^{-2} s^{-1}. The average efficiency of the proportional counters is 0·5 in the energy range and is insensitive to the energy spectrum of the source. Therefore

$$I_{\mathrm{Sgr}\,\gamma-1}(1{\cdot}5\text{–}6\ \mathrm{keV}) < 0{\cdot}80\ \text{photons cm}^{-2}\ \mathrm{s}^{-1}$$

This upper limit, which corresponds to three standard deviations of the background rate, is ~20 per cent of the intensity of Crab Nebula[3]. With an instrument similar to that which detected Sgr γ-1, Frye *et al.* have set an upper limit (95 per cent confidence) for γ-rays from the Crab Nebula[4].

Table 1. X-RAY AND γ-RAY INTENSITIES OF Sgr γ-1 AND CRAB NEBULA

Source	I (1·5–6 keV) (photons cm^{-2} s^{-1})	I (> 50 MeV) (photons cm^{-2} s^{-1})	α
Sgr γ-1	< 0·8	$(3 \pm 1) \times 10^{-5}$	< 2·1
Crab Nebula	4·5	$< 1{\cdot}7 \times 10^{-5}$	> 2·25

The X-ray and γ-ray flux data from Sgr γ-1 and the Crab Nebula are summarized in Table 1. The last column gives the limits for the spectral index, α, assuming that both sources have a power law photon number spectrum $E^{-\alpha}\, dE$ from X-ray to γ-ray energies. It is also assumed that Sgr γ-1 has not changed appreciably in intensity between July 1967 and February 1969. For the Crab Nebula the energy spectrum can be expressed as $7\ E^{-2}$ in the energy range 1–500 keV (ref. 3), followed by a steepening at higher energies as indicated in Table 1.

In summary, assuming that Sgr γ-1 is a discrete γ-ray source[1] we can state that it has an intensity of less than one-fifth of the Crab Nebula in soft X-rays of 1·5–6 keV. Below 50 MeV, it has a spectrum flatter than that of the Crab Nebula.

I thank Professor Hale Bradt, Professor S. Rappaport and Dr G. Spada for comments and for unpublished results.

Anorthosites in the Early Crust of the Earth and on the Moon

THE recent report from Houston[1] proposed that the lunar highlands may be composed "predominantly" of anorthosite and gabbroic anorthosite. O'Hara has therefore suggested that some of the Pre-Cambrian anorthosites may be reworked slices of the Earth's primordial crust. The aim of this report is to present evidence for such a relationship between lunar and early terrestrial anorthosites. Apart from the suggestion by Olsen[2], this has not been considered in the literature on either the lunar samples or on the evolution of the Earth–Moon system. In their comparisons of the lunar anorthosites with terrestrial rocks, Wood *et al.*[3] have followed the commonly accepted idea that there are only two varieties of anorthosites—the massive Adirondack and the stratiform Bushveld types. There is also a third type, however (first recognized as such by Harpum[4] and re-emphasized by Bridgwater[5]); a layered calcic anorthosite found in some high-grade basement terrains. Anorthosites in this third group are mostly the oldest plutonic rocks in the crust with any decipherable mode of origin, having been formed more than 3,000 m.y. ago and possibly as old as 3,500 m.y., and they are extremely similar chemically to the lunar anorthosites. Indeed, the similarities are enough to suggest that these are the first terrestrial rocks to have any marked affinities with those on the Moon.

The areas in the world where these Group III anorthosites occur are (Fig. 1): (1) West Greenland[6–9], (2) Southeast Greenland[10], (3) North Lewis, Scotland[11], (4) Messina/Soutpansberg, Rhodesia[12,13], (5) Sakeny, Madagascar[14], (6) Sittampundi, Madras, India[15], and (7) Kondapalli, India[16]. The rocks belong to pre-orogenic bodies situated

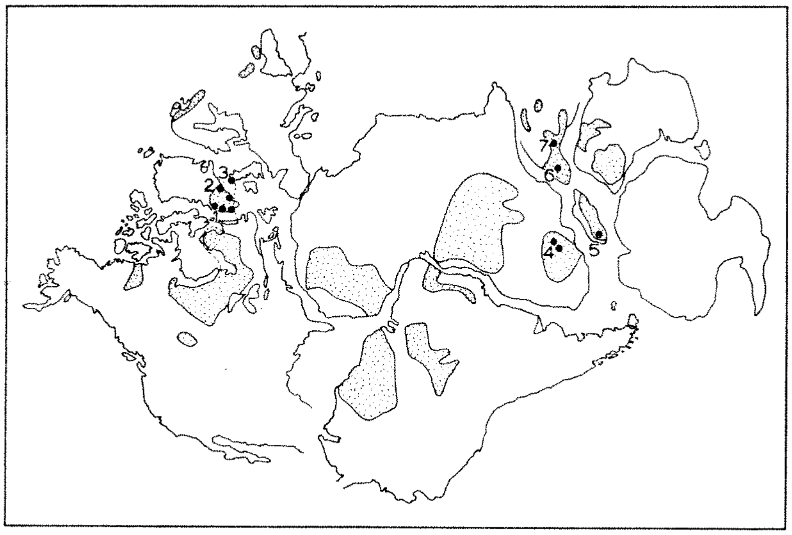

Fig. 1. Localities of early Pre-Cambrian Group III anorthosites situated within the Archaean (> 2,000 m.y.) cratons (see text). Modified after Hurley and Rand[24].

mostly in the oldest parts of the Archaean cratons, but only one radiometric age determination has been made on the actual rocks concerned: the 3,210 m.y. K/Ar date on hornblendes from an amphibolite within the Fiskenaesset complex, West Greenland[17]. A whole rock Rb/Sr or Pb isotope date on this complex might be expected to give a greater age, and therefore the time of formation of the anorthositic complex might be as much as 3,500 m.y. ago. In comparison, there seems to be general agreement[3,18] that the anorthosites on the lunar highlands formed before the mare lavas which crystallized in the period 3,600–3,800 m.y. (ref. 1).

These early Archaean Group III anorthosites have suffered the orogenic effects of one or more periods of regional metamorphism and deformation, with the result that they now occur as recrystallized tectonic pods and slices. The rocks themselves are remarkably well preserved, however, probably because an original plagioclase–orthopyroxene–clinopyroxene igneous assemblage was recrystallized isochemically into a similar metamorphic assemblage.

They are fine-grained, white granular rocks which include true anorthosites (> 90 per cent plagioclase), gabbroic anorthosites (77–90 per cent plagioclase) and anorthositic gabbros (< 77 per cent plagioclase). Where best preserved (Fiskenaesset, Sittampundi, Messina) they form extensive layered stratiform sheets with major units of anorthosite, amphibolite, peridotite and pyroxenite occurring as conformable layers (maximum thickness 6 km) in granitic gneisses. Where further deformed they survive as relic tectonic lenses, often in reworked gneisses (Lewis). There is a considerable amount of this type of anorthosite in early Archaean catazonal regions. In West Greenland, where they are best preserved, there are at least 400 km of exposed anorthositic layers[6].

The lunar and terrestrial Group III anorthosites are characterized by their calcic plagioclases, low Ti and high Ca and Al contents (Table 1).

But the chief diagnostic features of the lunar and Group III anorthosites (or associated rocks) are that they are commonly chromite bearing and that mafic minerals in both commonly have high Cr contents. All the chromites have very similar Cr : Fe ratios of about 1·0 (refs. 15, 19 and 20) which distinguishes them from Bushveld type anorthositic chromites where the ratio is 1·5. Interstitial pigeonite and augite in the lunar gabbroic anorthosite have Cr contents of 0·6 and 6·0 per cent respectively[19], while mafic minerals in some of the West Greenland rocks are rich in Cr even when there is no chromite present. The ultrabasic rocks within the Sakeny and Kondapalli anorthosites contain chromite and the Sittampundi, Fiskenaesset and Messina anorthosites are chromite layered.

Table 1. COMPOSITION OF ANORTHOSITES

	Lunar (2 samples[3])	Terrestrial (9 samples[6,13 15])
Plagioclase	An_{96-98}	mostly An_{85-100}
TiO_2	0– 0·3%	0– 0·4%
CaO	14·1–17·5%	14·0–21·0%
Al_2O_3	27·3–33·8%	25·5–33·2%

The evidence suggests that the Group III anorthosites are stratiform igneous cumulates separated from their source rocks; the source region could well be the layers of gabbroic and peridotitic differentiates at the base of the continental crust[21]. At present it is impossible to be certain how these rocks were emplaced or developed their present form. A flotation mechanism could be envisaged (see Wood *et al.*[3] and Anderson *et al.*[18] for the lunar anorthosites) involving separation of early calcic low density plagioclases from their underlying more basic differentiates, but this may meet serious problems when the associated heavy chromites are considered. The extent to which some layers were emplaced as tectonic slices into higher levels of the sialic crust is also uncertain.

There is, however, evidence that some anorthosite made its way into high structural levels to be introduced along cover-basement contacts (the Soutpansberg anorthosites formed below arenaceous sediments[13]) and even into the supracrustal deposits themselves (anorthosites occur in some greenstone belts[22]). This may mean that the Group III anorthosites remained mobile longer than their lunar counterparts and were therefore emplaced into different crustal levels at different times in the early Archaean.

Although there are many unknowns concerning these early Pre-Cambrian calcic anorthosites, it is important to recognize their existence as an integral group. On account of their extreme age, their compositional similarities with the lunar anorthosites and dissimilarities with other known terrestrial igneous rocks (chemically they are only comparable with the chromiferous grospydite inclusions in kimberlite pipes[23]), it is suggested that they are fragments of (primordial ?) layered differentiates formed early in the evolution of the Earth. This suggests that both planetary bodies went through parallel stages of development as far as the anorthosite event is concerned, and thus that the Moon may not be so dissimilar to the Earth as previously suspected.

My work on the anorthosites of West Greenland was made with the Geological Survey of Greenland, Copenhagen, and current work is being supported by the Natural Environment Research Council, London.

Anomalous Propagation of Elastic Energy within the Moon

THE records of the seismographs left on the lunar surface by the Apollo 11 and Apollo 12 missions have been discussed by Latham *et al.*[1]. From the behaviour immediately following impact of the Apollo 12 ascent stage and similar events present on the records before and after, they have inferred that energy propagation as elastic waves over large distances can be represented as a diffusive process in a low loss elastic continuum. They calculate a diffusion coefficient of ~ 1 km^2 s^{-1} and a specific dissipation function $Q \sim 3{,}600$ at a frequency of 1 Hz. If we use the time delay between the Apollo 12 impact and the commencement of the signal as the propagation time of an unscattered wave, we deduce a wave velocity of ~ 3 km s^{-1} and a scattering length $\sim 0{\cdot}5$ km. They emphasize that such a medium is quite unknown on Earth.

We wish to point out a few observations that encourage one to pursue this model for the Moon:

(i) The experiments of one of us (B. I. P.) on the measurement of Q in porous terrestrial rocks consistently show that Q increases when the ambient air pressure is reduced. At $\sim 10^{-2}$ torr, the limit of evacuation in these experiments, Q is typically five times greater than at atmospheric pressure. The effect is reversible and subsidiary experiments suggest that it is connected with an exchange of water $< 0{\cdot}05$ per cent by weight. Although indirect arguments[2] have been given that the lunar rocks did not acquire this amount of water under laboratory conditions, we suspect that the laboratory Q values of lunar rocks obtained by Kanamori *et al.*[3] (~ 10) at one atmosphere may not be representative. Obviously it will be necessary to make Q measurements on lunar rocks that have been kept under high vacuum.

(ii) The experiments of Grossman *et al.*[4] demonstrate that the surfaces of lunar material cleft under ultra high vacuum adhere when placed in contact. If the *in situ* scattering length just referred to is taken as the typical linear dimensions of separate blocks, the normal stresses present at the contact points would be more than adequate to maintain adhesion at the stress levels of the seismic wave.

(iii) Orowan[5] has suggested that stress waves through a medium may have rapidly increasing Q as the stress amplitude tends to zero. He suspects that if relative displacements of opposing crack faces approach interatomic distances the effective friction decreases to zero. This idea is perhaps not distinct from the concept of adhesion mentioned under (ii) (the maximum amplitude of the Apollo 12 signal was ~ 30 Å).

Perhaps the most important factor to emphasize is that although Q appears as a property of the medium in a continuum theory, from a structural point of view, if the material is an aggregate, the overall Q is sensitive to the state of the surfaces that make contact. Merely to postulate that the near surface region of the Moon is such an effective scattering medium probably ensures that no gas pressure can build up within it to destroy the adhesiveness of the bearing surfaces. The concept of the lossless "welded" contact mentioned by Latham *et al.*[1] seems to have some empirical support in this particular environment.

We thank J. C. Savage who supervised the experiments mentioned in section (i).

Quasars behind Clusters of Galaxies

A SYSTEMATIC search for quasi-stellar objects associated with clusters of galaxies was started by Sandage and Miller[1], but was discontinued when no cluster was found near 3C 48. The search has been resumed recently by Bahcall, Schmidt and Gunn[2]. Bahcall[3] found twenty-one QSOs with redshifts larger than $z = 0{\cdot}2$ in the direction of Zwicky clusters. In all these cases the redshifts of the QSOs are considerably larger than the redshifts of the associated clusters. Assuming that the redshifts are cosmological, all the twenty-one QSOs would be at considerable distances behind the clusters. This suggests a simple explanation of the association of clusters with QSOs; namely, that QSOs are gravitational lens images[4].

The bending of light in the gravitational field of astronomical objects is a well established phenomenon. The recognition of the possible existence of gravitational lenses can be traced as far back as 1919, when Lodge[5] noted that a gravitational lens does not have a real focal length and produces two images. All the papers published before 1965 discuss the effect in Euclidean space, with the deflecting mass confined within a radius which is small compared with the distance by which the light rays bypass the deflector. The solution in non-Euclidean space for the situation when the light rays pass through the mass distribution of the deflector and for relativistic cosmological models was worked out by J. M. B.[4] and J. M. B. and M. F. B.[6]. Recently, Saslaw, Faulkner and Strittmatter[7] as well as ourselves[8] applied the gravitational lens effect to explain pulsating radio sources.

Every galaxy is a potential gravitational lens for all objects properly lined up behind it. The foreground galaxy acting as the lens will produce a greatly distorted image, but in amplified brightness. The image has the shape of two thin crescents, which may coalesce to a thin ring. A small galaxy of 10^{10} $M_{\odot}$ amplifies by more than five magnitudes the brightness of any object which happens to lie within 2×10^{-8} rad of the line of sight through its gravitational centre. From Wagoner's[9] calculations we know that to a redshift of $z = 2$ we see 3 to 15 per cent of all galaxies through a foreground galaxy. While not all of these intervening galaxies will be properly aligned with a suitable object to produce a large brightness amplification, the presence of a large number of gravitational lens images over the sky is self-evident. We have shown that if the object of the lens is a Seyfert galaxy, the image will be similar in all eight characteristics to the objects accepted as representative of QSOs.

It is generally assumed that at least 50 per cent of galaxies are members of clusters of galaxies. Consequently, if QSOs are gravitational lens images with 50 per cent of the lenses being cluster galaxies, we should expect eighty out of the 160 or so known QSOs to be seen behind a cluster. Unfortunately, with the usual observational techniques, clusters of galaxies can be identified as such only up to $z = 0{\cdot}3$ or, with the improved technique of Sandage and Miller, up to about $z = 0{\cdot}4$. This may explain why Bahcall has found only twenty-one QSOs behind clusters.

3C 273 is an interesting case of the connexion of a QSO with a cluster. The brightness variations of this object, monitored over eighty years, show a pattern which is similar to a random process in which a finite band of the lowest frequencies contains relatively more power than the adjacent spectrum. The dominant frequency was found to be 0·06 yr^{-1} (ref. 10). Such a brightness variation pattern is expected if 3C 273 is a gravitational lens image and the optical axis of the lens scans the object (the nucleus of a Seyfert galaxy) which itself consists of a large number of discrete secondary light sources. As a simple computation as well as a trial scan over a random source field shows, the pattern of the variations of 3C 273 can be faithfully reproduced at a scanning speed of 25,000 km s^{-1} in the frame of the object. Considering the rotation of the galaxy, that of the supergalactic system and the galactic and supergalactic coordinates of 3C 273, such an extremely high scanning speed would follow if the lens were nearer than about 12 Mpc. As 3C 273 is in the direction of the Virgo cluster, which is at a distance of 11·4 Mpc, this suggests that the lens is a compact galaxy (of the type Zw 0930-5527, or Zw 1117-5141) in the Virgo cluster. The nuclei of the two compact galaxies mentioned are small enough that from a distance of 12 Mpc their apparent diameter would be less than one arc s. The faint wisp-like nebulosity seen near the radio component A of 3C 273 could then be the irregular nebulosity often accompanying compact galaxies.

We can estimate the chance that one of the galaxies belonging to a cluster of galaxies would act as a lens for a remote nucleus of a Seyfert galaxy. The average absolute magnitude of Seyfert galaxies is $-19{\cdot}7 \pm 0{\cdot}2$ (ref. 11), so a brightness amplification of five magnitudes would be enough to raise the luminosity of the image to the range of QSO luminosities. The average distance of the tweny-one clusters in Bahcall's list is $\bar{d}_{\mathrm{d}} = 210$ Mpc, while the associated QSOs are distributed over a distance range of 780 Mpc to 6,570 Mpc (using $H = 100$ km s^{-1} Mpc^{-1}). We may write the amplification factor of a gravitational lens in the simplified form[12]:

$$A \geq 2(C/d_{\mathrm{d}})^{1/2}/\beta \text{ with } C = GM/c^2$$

Here M is the mass of the lens and β the apparent angular distance of the object from the optical axis of the lens. (The gravitational radius of the lens galaxy (10^{-2}–10^{-4} pc) is always very small compared with the distance (0·1–10 kpc) by which the light rays arriving from the object and focused on the observer bypass the gravitational centre of the lens galaxy. Consequently, all calculations on the size and the brightness of the image can use simple geometrical optics. Whenever the cosmological distance of the lens and of the object is large, the equations have to be written in the metric of the cosmological model chosen to represent the universe. In the case discussed here, when we want to compute the statistical probability of finding an image behind a cluster of galaxies, the latter being close to us, the use of Euclidean geometry suffices.) Assuming that cluster galaxies are on the average $2 \times 10^{10}\ M_{\odot}$ ($C = 10^{-3}$ pc), each of them will produce from every object located in a truncated cone of half-angle $4{\cdot}36 \times 10^{-8}$ rad behind the galaxy an image of the object brightened by more than five magnitudes. This truncated cone extends from, say, 600 Mpc to 10,000 Mpc and the number of galaxies per Mpc^3 down to an absolute magnitude of -14 is 0·47 (ref. 13), while Seyfert galaxies are estimated to be 2 per cent of all galaxies. The volume of the truncated cone behind each cluster galaxy is 2×10^{-3} Mpc^3 and thus contains $1{\cdot}9 \times 10^{-5}$ Seyfert galaxies. The chance of finding an image with the properties of a QSO behind an average cluster containing about 130 galaxies is therefore 1 in 400.

We must realize, of course, that in observable clusters a large or medium galaxy cannot act as a lens of a "quasi-stellar" object, because it would be seen in front of the image. The entire morphological configuration would not be of stellar appearance, but rather similar to that of an N-type galaxy[14]. The three types of galaxies which, at short distance from us, could act as lenses without being seen to extend beyond the star-like image are compact galaxies, dwarf galaxies and dead galaxies.

We have given already an example (3C 273) of a compact galaxy acting as a lens, where the lens is invisible in spite of being at a distance of only 12 Mpc. Zwicky's (unpublished) catalogues of compact galaxies contain two thousand objects. Considering the lower average luminosity of compact galaxies, we may infer that the number of compact galaxies is at least equal to or larger than the number of normal galaxies.

Dwarf galaxies, such as are found in the local group of galaxies (NGC 147, NGC 185, NGC 205, NGC 221, NGC 1613, NGC 6822 and those in the Sculptor, Fornax, Wolf–Lundmark and Leo systems) with luminosities below -16, would be too faint to be seen at a distance of 200 Mpc, even if their diameter is more than 1 kpc. According to de Vaucouleurs's estimate[11] the number of dwarf galaxies ($-16 < M < -11$) could be a hundred times larger than the number of normal galaxies. Assuming a ten times larger number of dwarf galaxies but at the same time a ten times smaller mass ($2 \times 10^9\ M_{\odot}$), the chance of finding a QSO behind a given cluster of galaxies is, as before, 1 : 400.

One famous puzzle of astronomy is that the total mass of a cluster of galaxies is twenty to fifty times larger than the total mass of all visible galaxies in the cluster. The same puzzle appears in cosmology where the mean density of matter in space, computed from the mass of visible galaxies (7×10^{-31} g cm^{-3}), turns out to be lower by two orders of magnitude than would follow from relativistic models of the universe. Peebles[15] has suggested that there may be many dead, invisible galaxies in the intergalactic space. Should the mass of these invisible galaxies represent the explanation of the mass discrepancy, then our estimate (1 : 400) of the chance of finding a QSO behind a cluster of galaxies would increase by a factor of between twenty and fifty.

Our final conclusion is that there is a good chance that if a QSO is behind a cluster of galaxies, this QSO is a gravitational lens image produced by a cluster member (small, compact, dwarf or dead galaxy), acting as the lens on an object (Seyfert galaxy), situated at the cosmological distance corresponding to the redshift of the QSO.

Shape of the Crab Pulsar and its Period Fluctuations

RICHARDS *et al.*[1] have recently recorded sinusoidal variations in the arrival times of radio pulses from NP 0532 with a period of about three months and an amplitude $\Delta\tau = 6 \times 10^{-4}$ s. This effect can be interpreted in terms of genuine sinusoidal variations of the circular frequency of the Crab pulsar

$$\Omega(t) = \Omega(1 + A \cos \omega t) \qquad (1)$$

where $\Omega \simeq 200$ s^{-1}, $\omega \simeq 10^{-6}$ s^{-1}, $A \simeq 10^{-10}$. Equation (1) can be explained by the widely accepted oblique rotator model[2-4] simply by investigating an interesting consequence of the possible ellipticity of the neutron star. To account for the history and energy balance of the Crab Nebula[3], an upper limit must be placed[4,5] to this ellipticity, such that the gravitational quadrupole radiation dominates the magnetic dipole radiation only in the early life of the pulsar. It turns out that the explanation given here for the anomalies in the pulse arrival times provides in the end an even stronger limit to the deviations from spherical symmetry allowed in a neutron star.

In the oblique rotator, because of the emission of low frequency electromagnetic waves, a non-conservative torque is applied to the neutron star. The torque is responsible for slowing down[4] the rotation at a rate in good agreement with the observations, and probably for aligning the magnetic axis with the rotation axis (F. C. Michel at the Princeton pulsar meeting, November 1969). Both effects are secular (with time scales of thousands of years for the Crab pulsar), so that over periods of the order of months, the angular momentum vector **M** of the pulsar may be considered constant in direction as well as in magnitude. The pulsar accordingly behaves as a free top.

The model assumed here for NP 0532 is a slightly aspherical ellipsoid instead of a perfect sphere. Examples of such configurations in rotating bodies are well known in Newtonian gravitation (Jacobi ellipsoids) and no *a priori* argument (except for a lifetime which is possibly much too short because of gravitational radiation) can rule out their existence in general relativity. The motivation adopted here, however, for the lack of axial symmetry is magnetic, not rotational. Let x_1, x_2 and x_3 be the three principal axes of inertia of the neutron stars and let the corresponding moments of inertia satisfy the inequalities

$$I_1 < I_2 < I_3 \qquad (2)$$

With the magnetic field axis along the direction of greater elongation, x_1, let **M** be at a small angle with x_3. In other words, let the rotation be nearly around x_3, but not exactly (off axis rotation has already been investigated in connexion with other phenomena in pulsars[6]). An oblique rotator is thereby realized, the free motion of which is well known[7]. A new frequency, ω', is associated with the system in addition to the main frequency of rotation, $\Omega \simeq \Omega_3$

$$\omega' = \Omega \varepsilon_1 \varepsilon_2 \qquad (3)$$

where

$$\varepsilon_1^2 = \frac{I_3}{I_1} - 1,\ \varepsilon_2^2 = \frac{I_3}{I_2} - 1 \qquad (4)$$

are two small quantities. ω' appears in a variety of effects: in particular, it turns out[7] that the components of **M** along x_1 and x_2 are given by

$$\begin{aligned} M_1 &= aM\varepsilon_2 \cos \omega' t \\ M_2 &= aM\varepsilon_1 \sin \omega' t \end{aligned} \qquad (5)$$

where a is the small-amplitude constant related to the mean square angle θ between **M** and x_3 by

$$a^2 = \frac{2\theta_2}{\varepsilon_1^2 + \varepsilon_2^2} \qquad (6)$$

Obviously Ω_3 differs from $|\mathbf{\Omega}| = \Omega$ for terms of the order a^2, which can be evaluated by means of the appropriate Euler's equation. By using equation (5), one finds that

$$\Omega_3 = \Omega \left[1 - \frac{1}{4} a^2(\varepsilon_1^2 + \varepsilon_2^2) + \frac{1}{4} a^2(\varepsilon_1^2 - \varepsilon_2^2) \cos 2\omega' t \right] \qquad (7)$$

The constant of integration of order a^2 is really immaterial: the choice in equation (7) satisfies $M_1^2 + M_2^2 + M_3^2 = M^2$. The kinetic energy of rotation is thus

$$K = \frac{1}{2} I_3 \Omega^2 (1 + a^2 \varepsilon_1^2 \varepsilon_2^2)$$

According to equation (7) the ellipsoidal pulsar does not rotate on itself at a fixed rate $\Omega_3 < \Omega$, but slower or faster with frequency $2\omega'$, which may, of course, account for equation (1). The assumption $\varepsilon_1 \neq \varepsilon_2$, or relations (2), is then crucial, whereas a flattened spheroid with axial symmetry would not be adequate. It is assumed here that, although ε_1^2 and ε_2^2 are mainly rotational deformations, $(\varepsilon_1^2 - \varepsilon_2^2)$ is determined by magnetic effects.

For the Crab pulsar $\omega/\Omega \simeq 10^{-8}$, so that in order to justify $\omega \simeq 2\omega'$ one must have from equation (3) $\varepsilon_1 \varepsilon_2 \simeq 10^{-8}$, or

$$\varepsilon_1^2 \text{ and } \varepsilon_2^2 \simeq 10^{-8} \qquad (8)$$

The rotational deformations of a general relativistic neutron star have been evaluated under the assumption of axial symmetry[8]. For an ellipsoid such computations turn out to be forbiddingly difficult. In a Newtonian approximation every fluid model will have rotational deformations of the moment of inertia, $\Delta I/I \simeq \varepsilon_1^2 \simeq \varepsilon_2^2$ of the order[9] of $\Omega^2/(2\pi G \rho_c)$. This implies for our case

$$\varepsilon_1^2 \text{ and } \varepsilon_2^2 \simeq 10^{-4} \qquad (9)$$

rather than equation (8).

Strictly speaking, the rotational deformations in a general relativistic star are to a certain extent smaller than in their Newtonian counterpart[10] (because the dragging of the inertial frame implies, among other things, a reduction of the centrifugal force[8]). This effect can hardly be enough to reconcile equations (8) and (9), however.

If the present explanation for the period fluctuations proves correct, therefore, the discrepancy between equations (8) and (9) will by itself point to the existence of strong forces in a neutron star forbidding relatively wide deformations. A very thick solid crust[11] might perhaps be adequate. The geometrical deformations, $\Delta R/R$, implied by equation (8) are exceedingly small, the equatorial radius being only 10^{-2} cm longer than the polar radius. In a sense it is gratifying that the recent quake[12,13] on the Crab pulsar implies[11] only a minor crust readjustment of the order of 10^{-3} cm.

In terms of the assumed magnetic perturbation $\delta_M \ll 1$

$$\varepsilon_1^2 = \varepsilon_2^2 (1 + \delta_M) \qquad (10)$$

the magnitude of the variable part of the quadrupole moment is clearly $D \simeq I_3 \varepsilon_2^2 \delta_M$. The corresponding gravitational radiation energy loss[14] becomes

$$-\frac{dK}{dt} \simeq \frac{G}{c^5} (I_3 \varepsilon_2^2 \delta_M)^2 \Omega^6 \simeq 10^{28} \delta_M^2 \text{ erg s}^{-1}$$

within an irrelevant numerical factor. This is so small in comparison with the energy requirement of the Crab Nebula and assumed magnetic dipole loss[2-4] as to make the gravitational damping totally insignificant at the present time. No contradiction arises therefore with the general model (see also ref. 15).

By making use of equations (6), (7) and (10) the amplitude A in equation (1) becomes

$$A = \frac{1}{2}\,\theta^2\,\frac{\varepsilon_1{}^2-\varepsilon_2{}^2}{\varepsilon_1{}^2+\varepsilon_2{}^2} = \frac{1}{4}\;\theta^2\delta_M \qquad (11)$$

For a field of 10^{12} G the magnetic effects are likely to be rather superficial. They may be calculated within a certain model[4] or, very roughly, simply by taking δ_M equal to the ratio of the magnetic to the ordinary pressure. For an indicative density of 10^9 g cm^{-3} in white dwarf material, $\delta_M \simeq 10^{-4}$. This in turn reproduces from equation (11) an amplitude $A \simeq 10^{-10}$ for a sensible deviation $\theta \gtrsim 10^{-3}$.

Much more remains to be seen before definite conclusions can be reached, but it seems that the phenomenon in itself emphasizes the precision of the pulsar clock and supports the notion[16] of a beacon on the neutron star surface rather than farther out, accurate timing being harder in the second case. Our explanation of equation (1) is appealing because it does not require new assumptions about pulsar structure and it has a considerable flexibility.

A difficulty, however, may be that the present state of the crust theory does not seem to yield the required stiffness (equation (8)). It is also possible that the frozen crust retains much of the flattening of the original fluid configuration.

We thank Drs H. Y. Chiu and M. A. Ruderman for discussions and Dr R. Jastrow for hospitality at the Institute for Space Studies. C. C. holds an ESRO fellowship and F. O. is an NAS–NRC research associate.

Possible Clues to the Early History of the Solar System

ONE problem in connexion with the nucleosynthesis of the light elements, D, Li, Be and B, has been to decide whether preplanetary matter at an early stage of the solar system was intensely irradiated by solar particles. First put forward by Hayakawa[1] and Fowler, Greenstein and Hoyle[2], and later modified by others[3-5], this notion has motivated searches for anomalies in the isotopic abundances of several elements in meteorites[6-16]. Within experimental accuracies, however, these isotopic abundances were identical with those of terrestrial matter except for lithium[11,13,16], and because of recent theoretical considerations the tendency is to abandon the irradiation mechanisms of Fowler, Greenstein and Hoyle[17,18]. But it seems to us worthwhile to continue the study, on one hand by improving the experimental accuracy, and on the other by looking for abundance anomalies caused by other types of nuclear reactions.

According to Mitler, the mean proton energy of 570 MeV assumed by Fowler, Greenstein and Hoyle is too high[3], based on recent observations of solar flare particles. Hayakawa has also used, in his latest article[5], the spectra of contemporary solar particles. In this case isotopic anomalies in the product nuclides from high energy nuclear reactions such as ^{50}V or ^{54}Cr would be less probable. The neutron-induced reactions will also be less important because of the lower neutron production with softer primaries. We therefore looked for other nuclear reactions induced by low energy protons and alpha particles and found that ^{138}Ba(p,n)^{138}La and ^{180}Hf(p,n) ^{180}Ta are the most suitable, because ^{138}La and ^{180}Ta are extremely low in cosmic abundance compared with the respective target nuclides ^{138}Ba and ^{180}Hf. (Brancazio *et al.*[19] have investigated similar reactions, but their discussion refers to bombardment in stellar surfaces.) Table 1 shows the results of our calculations for these two reactions as well as other possible side reactions that may give the same product nuclei. For the calculation of average cross-section $\bar{\sigma}$, we used Barbier's semi-empirical $\sigma(E, AT)$ function[20] as no measured excitation functions are available. The shape of the integral proton spectrum was assumed to be $\varphi(>P) = \varphi_0 \exp(-P/P_0)$ according to the solar flare observation[21], where φ is the total flux for the event; P is the rigidity (MV/nucleon); and P_0 the characteristic rigidity for the solar event, here taken to be 100 MV. For the neutron spectrum in the range 2 to 20 MeV we used the differential form $\varphi = k(1 + 0{\cdot}01\ E^{-1} + 1{\cdot}1 \times 10^{-5}\ E^{-2})$ given by Arnold *et al.*[22], where E is in BeV. The abundance ratios of product nuclide to target nuclide in the preplanetary matter were taken to be the same as the cosmic abundances for non-volatile elements and Cameron's new cosmic abundances were employed[23]. (The product nuclide here means the same nuclide species present in preplanetary matter as the product of the nuclear reaction on the assumed target.) The last column of Table 1 shows a measure of the sensitivity of each reaction, that is, the integrated flux of irradiating particles that may cause a 1 per cent relative anomaly in isotopic abundance ratio. The calculation assumes uniform irradiation in the same way as done by Burnett *et al.*[9] for ^{40}K. In order to compare with other indicator elements for proton irradiation, we calculated the corresponding total flux φ_0 for each reaction, assuming the same integral rigidity function for the event. Table 2 shows the values of φ_0 with $P_0 = 50$, 100 and 200, covering the characteristic rigidity for present day solar flares. It can be seen that ^{138}La and ^{180}Ta are the most sensitive

Table 1. NUCLEAR REACTIONS POSSIBLY GIVING RISE TO THE ISOTOPIC ABUNDANCE ANOMALY OF ^{138}La AND ^{180}Ta

Reaction	Product/ target	σ (mbarn)	Integrated fluxes for 1 per cent anomaly (cm^{-2})
^{138}Ba(p,n)^{138}La	$9{\cdot}5 \times 10^{-5}$	200 (10–50 MeV p)	$4{\cdot}8 \times 10^{18}$p
^{139}La(n,2n)^{138}La	$8{\cdot}9 \times 10^{-4}$	500 (2–20 MeV n)	$1{\cdot}8 \times 10^{19}$n
^{139}La(p,pn)^{138}La	$8{\cdot}9 \times 10^{-4}$	70 (10–50 MeV p)	$1{\cdot}3 \times 10^{20}$p
^{138}Ce(n,p)^{138}La	0·11	< 100 (2–20 MeV p)	$> 1{\cdot}1 \times 10^{22}$n
^{180}Hf(p,n) ^{180}Ta	$4{\cdot}8 \times 10^{-5}$	70 (10–50 MeV p)	$6{\cdot}9 \times 10^{18}$p
^{181}Ta(n,2n)^{180}Ta	$1{\cdot}2 \times 10^{-4}$	500 (2–20 MeV n)	$2{\cdot}4 \times 10^{18}$n
^{181}Ta(p,pn)^{180}Ta	$1{\cdot}2 \times 10^{-4}$	50 (10–50 MeV p)	$2{\cdot}4 \times 10^{19}$p
^{180}W (n,p)^{180}Ta	$1{\cdot}25 \times 10^{-2}$	< 50 (2–20 MeV n)	$> 2{\cdot}5 \times 10^{21}$n

Table 2. SENSITIVITY OF INDICATOR NUCLIDES FOR PROTON IRRADIATION

Indicator nuclide	Experimental limit on abundance variation (per cent)	Integrated fluxes for effective proton energy range: Energy E (MeV)	Rigidity P (MV)	$\varphi(P)$†	φ_0(cm^{-2})*: $P_0=50$	$P_0=100$	$P_0=200$
^{7}Li/^{6}Li	2	>75	>376	1×10^{18}	2×10^{21}	4×10^{19}	7×10^{18}
^{36}S	0·1	>1000	>1680	10^{20}	4×10^{34}	3×10^{27}	4×10^{23}
^{54}Cr	1	>30	>235	3×10^{19}	3×10^{21}	3×10^{20}	1×10^{20}
^{40}K	1	>500	>1100	2×10^{19}‡	7×10^{28}	1×10^{24}	5×10^{21}
^{50}V	1	>100	>440	$2·5\times10^{17}$	2×10^{21}	2×10^{19}	2×10^{16}
^{138}La	1	50–10	305–130	5×10^{16}	6×10^{19}	2×10^{19}	$1·5\times10^{19}$
^{180}Ta	1	50–10	305–130	7×10^{18}	9×10^{19}	3×10^{19}	2×10^{19}

* φ_0 has essentially the same meaning as $\Delta\varphi$ for the solar flare spectrum in Table 3 of Balsiger, Geiss and Lipschutz[10]. The difference is that the latter is based on the power function of energy and is integrated for $E > 10$ MeV, while the former is the total flux based on the rigidity function.

† $\varphi(P)$ for the nuclides other than ^{138}La and ^{180}Ta was taken from Burnett, Lippolt and Wasserburg[9], who had used a different proton spectrum from ours. This would not make any difference, because the excitation functions for these high energy protons are nearly flat and consequently the reaction yield is independent of the shape of spectrum.

‡ The value given by Burnett, Lippolt and Wasserburg[9] was recalculated; their calculation seems not to have taken into account the decay of ^{40}K during the past $4·5\times10^9$ yr.

for soft flares with $P_0 < 100$ while ^{50}V and lithium isotopes are the most sensitive for hard flares with $P_0 > 100$. A preliminary result on ^{50}V was reported by Balsiger *et al.*[10]. Because of our lack of knowledge about the early rigidity of the solar particles, effects of both soft and hard particles should be investigated, but because little attention has been given to the softer side, it is important to study ^{138}La and ^{180}Ta.

Another merit of ^{138}La and ^{180}Ta is that the p,n reaction is efficient only when the irradiated matter is of low density like the clouds of gas or dust assumed by Hayakawa[5] (because of the short penetration range of low energy protons). This will give us information about the limits of the state of preplanetary matter at the time of irradiation.

One of us has measured[24] the isotopic abundance of ^{138}La in the Norton County achondrite but has found no anomaly within the experimental relative error of 2–3 per cent. We are preparing a similar experiment with better instrumental accuracy and on many kinds of meteorites.

Apart from the problem of the early stage of the solar system, these reactions, when combined with ^{56}Fe(p,n)^{56}Co, will be useful for the investigation of the history of solar flare activity from the lunar surface material.

We thank Professor H. Hamaguchi and Professor M. Honda for discussions.

A Generalized Hoyle–Narlikar Particle Theory

Hoyle and Narlikar[1] (HN) have developed a particle (rather than a field) theory of gravitation. This is based on Mach's principle such that the mass m_a of the particle a arises from all other particles of the universe. The mass function at a general point x due to a is defined as

$$m^{(a)}(x) = -\lambda \int \tilde{G}(X,A)\mathrm{d}a$$

where λ is a coupling constant and $\tilde{G}(X,A)$ a symmetric scalar Green's function which satisfies a simple wave equation. The mass m_a of the particle a is given by

$$m_a(x) = \sum_{b\neq a} m^{(b)}(x) = -\lambda \sum_{b\neq a} \int \tilde{G}(X,B)\mathrm{d}b$$

and thus depends on position. The physical significance of the mass field is that $m^{(a)}(x)$ is the inertia contributed by the particle a to another at the point x. The inertial mass of a particle is equal to the inertia contributed to it by all the other particles. Particle equations closely related to Einstein's field equations then arise from the variation of

$$J = -\sum_a \frac{1}{2} \int m_a \mathrm{d}a$$

Islam[2] points out that his work implies that the sign in the definition of $m^{(a)}(x)$ is correctly chosen. A change of sign does not affect the geometry or geodesics of particles but makes the sign of the gravitational constant, G, which appears in the particle equations, negative. The inertial mass m, however, of an isolated particle and the inertia contributed by it are both now negative. Thus $G > (<) 0$ means $m > (<) 0$ though the possibility arises in Einstein's theory of $G > 0$ and $m < 0$ and vice versa and, in this case, the geometry is different from the usual one.

The HN theory can, however, be easily extended to allow for particles which contribute either positive or negative inertias by making the definition

$$m^{(a_\nu)}(x) = (-1)^\nu \lambda_\nu \int \tilde{G}_\nu (X,A_\nu)\mathrm{d}a_\nu,\ \nu = 1,2$$

there being no summation over the νs. λ_ν is positive for $\nu = 1,2$. This can still be termed the "mass function at a general point x due to a_ν". Both of the $\tilde{G}_\nu$ are taken to obey wave equations of the type obeyed by the $\tilde{G}$ of the usual theory, such that

$$\Box \tilde{G}_\nu + \frac{1}{6} R\tilde{G}_\nu = -\delta^4/\sqrt{(-g)}$$

$m^{(a_1)}(x)$ and $m^{(a_2)}(x)$ contribute positive and negative inertia respectively. The definition

$$m_{a_\nu}(x) = \sum_{b\nu\neq a\nu} m^{(b_\nu)}(x)$$

can be made but cannot be termed the "mass of the particle a_ν at x" because it only takes into account particles of one type of inertia and not all the particles of the universe. Instead the mass of the particle a_ν at x must now be defined as

$$M_{a_\nu}(x) = \sum_{\nu=1,2} \sum_{a_\nu} m^{(a_\nu)}(x) - m^{(a_\nu)}(x)$$

This is the generalization of the physical significance of $m_a(x)$ and means that the mass of a particle is still contributed by all the other particles.

The action corresponding to that in the HN theory is

$$J = -\sum_{\nu=1,2} \sum_{a_\nu} \tfrac{1}{2} \int m_{a_\nu}\, \mathrm{d}a_\nu$$

$$= \sum_{\nu=1,2} (-1)^{\nu+1} \lambda_\nu \sum_{a_\nu < b_\nu} \int\int \tilde{G}_\nu\, \mathrm{d}a_\nu\, \mathrm{d}b_\nu$$

such that the particle equations formed by varying J with respect to g_{ij} and putting $\delta J = 0$ are

$$\left(R_{ij} - \frac{1}{2} g_{ij} R\right)\left[\sum_{\nu=1,2} \frac{(-1)^{\nu+1}}{\lambda_\nu} \sum_{a_\nu < b_\nu} m^{(a_\nu)} m^{(b_\nu)}\right] \tag{1}$$

$$= -3 g_{ip} g_{jq} T_m{}^{pq}$$

$$+ \sum_{\nu=1,2} \frac{(-1)^{\nu+1}}{\lambda_\nu} \sum_{a_\nu < b_\nu} [m^{(a_\nu)}(g_{ij} \Box m^{(b_\nu)} - m^{(b_\nu)}{}_{;ij})$$

$$+ m^{(b_\nu)}(g_{ij} \Box m^{(a_\nu)} - m^{(a_\nu)}{}_{;ij})$$

$$+ 2(m^{(a_\nu)}{}_{;i}\, m^{(b_\nu)}{}_{;j} + m^{(b_\nu)}{}_{;i}\, m^{(a_\nu)}{}_{;j} - \frac{1}{2} g_{ij} m^{(a_\nu)}{}_{;k} m^{(b_\nu);k})]$$

where

$$T_m{}^{pq} = \sum_{\nu=1,2} \sum_{a_\nu} \int m_{a_\nu}\, \delta^4 \sqrt{(-g)}\, \frac{\mathrm{d}a_\nu{}^p}{\mathrm{d}a_\nu} \frac{\mathrm{d}a_\nu{}^q}{\mathrm{d}a_\nu}\, \mathrm{d}a_\nu$$

The calculations follow the same lines as those in the normal HN theory.

This theory is obviously conformally invariant under the mapping

$$\bar{g}_{ij} = \Omega^2 g_{ij}, \qquad \overline{m}^{(a_\nu)} = m^{(a_\nu)}/\Omega$$

As in the HN theory, a smooth-fluid approximation of the theory can be made by writing

$$m_\nu(x) = \sum_{a_\nu} m^{(a_\nu)}(x)$$

in which case the particle equations become the field equations

$$\frac{1}{2} \sum_{\nu=1,2} \frac{(-1)^{\nu+1}}{\lambda_\nu} m_\nu{}^2 (R_{ij} - \tfrac{1}{2} g_{ij} R) = -3 T_{mij}$$

$$+ \sum_{\nu=1,2} \frac{(-1)^{\nu+1}}{\lambda_\nu} [m_\nu(g_{ij} \Box m_\nu - m_{\nu;ij})$$

$$+ 2(m_{\nu;i} m_{\nu;j} - \tfrac{1}{4} g_{ij} m_{\nu;k} m_\nu{}^{;k})] \tag{2}$$

The gravitational "constant" in these equations is proportional to $(m_1{}^2/\lambda_1 - m_2{}^2/\lambda_2)^{-}$ and can thus be positive, negative or infinite in different regions of space–time.

HN have shown how a particular conformal frame can be chosen in the case of the smooth-fluid approximation equations in which G is constant and that in this frame the Einstein equations result. Here there are two frames in which, after the mapping $\bar{g}_{ij} = \Omega^2 g_{ij}$ is made, $\bar{G}$ is constant. The first frame is when $\overline{m}_1$ and $\overline{m}_2$ are both constants, in which case Einstein's equations result. The second frame is when this is not so and Ω is now chosen so that $\overline{m}_1{}^2/\lambda_1 - \overline{m}_2{}^2/\lambda_2$ is constant and the field equations

$$R_{ij} - \tfrac{1}{2} g_{ij} R = -(6G/\alpha)(T_{mij} + S_{ij})$$

result. Here

$$S_{ij} = (\alpha/G)(\theta_i \theta_j - \tfrac{1}{2} g_{ij} \theta_k \theta^k)$$

$$\theta = \ln A[m_1/\sqrt{\lambda_1} + m_2/\sqrt{\lambda_2}]$$

$\theta_i \equiv \theta_{;i}$, α and A are constants and the bars have been dropped. These field equations are the scalar–tensor equations used in the HN field theory[3], the Brans–Dicke[4] theory and other theories.

Thus the most important and interesting result has been obtained that both the Einstein and scalar–tensor field equations arise in special frames under a conformal mapping of the field equations (2). As these themselves are the smooth-fluid approximations of (1), the generalized HN particle equations (1) play a very important part in that most of the particle and field equations normally used in relativistic-like theories can be derived from them.

Hawking[5] discussed an action which was a generalization of HN's action in that he introduced positive and negative gravitational charges analogous to electric charges. He also required the same number of positive and negative charges. But he did not extend the discussion to include any particle or field equations.

More details of the working and further results will be published later.

I thank Drs J. N. Islam, J. V. Narlikar and N. W. Taylor for discussions.

Geophysical Implications of the Interrelationship of the Geogravity and Geomagnetic Fields

RECENTLY there has been much interest in the geophysical implications of the satellite-determined gravity field, and one suggestion is that the low-degree gravity harmonics are associated with undulations at the core–mantle boundary[1-4]. Mathematical formulation[5] does indicate that any mass anomalies at the core–mantle boundary would be observable in the Earth's external potential. Indirect evidence in favour of this hypothesis would come from a strong correlation between the gravity and geomagnetic fields, because variations in the latter are attributed to sources located in the outer core. Egyed[3] pointed out a positive correlation between the satellite geoid[6] and the geomagnetic secular variations[7], but Coode and Runcorn[8] showed that this correlation was negligible when an improved satellite geoid[9] was used. Hide[4] has proposed, however, that certain magnetohydrodynamical considerations may suggest low amplitude, long wavelength irregularities in the core–mantle interface.

If the two fields are correlated only for a limited range of frequencies, their composite representations may not show any significant relationship because of the superposition of uncorrelated components. One must study the degree correlation function which is defined as the ratio of the degree cross covariance to the square root of the product of degree variances of the two force fields. Table 1 lists this function for the satellite-determined geopotential[10,11], the geomagnetic field due to internal

Table 1. COMPARISON OF THE GEOMAGNETIC AND GEOGRAVITY FIELDS

	Degree correlation function

8	−0·09	

sources[12] and the geomagnetic secular variations[13]. The pattern of the degree correlation function is more or less similar (our unpublished work) for other combinations of the recent geopotential solutions and the recent models of the non-dipole part of the geomagnetic field and its secular variations.

The degree correlation function between the anomalous gravity field and the non-dipole part of the geomagnetic field is significantly positive only for $n = 3$ and $n = 4$. For the remaining frequencies ($n > 4$), the function oscillates around zero. The positive correlation between the gravity field and the geomagnetic secular variations is therefore limited to $n = 3$ and $n = 4$ with an unmistakable peak in the third harmonic.

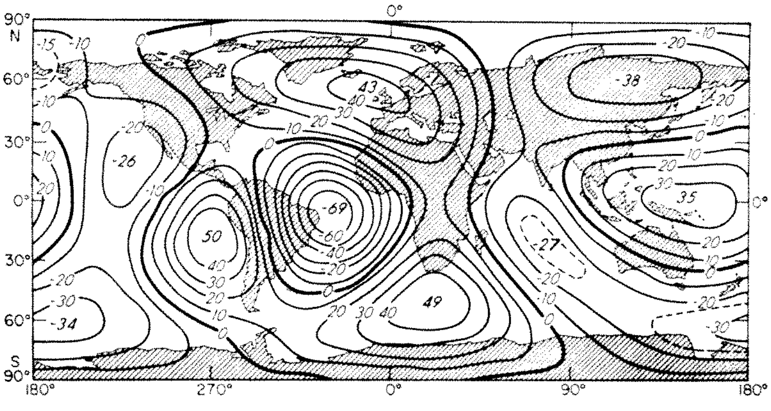

Fig. 2. Secular variations of the vertical component of the geomagnetic field arising from the third and fourth harmonics[13] for the epoch 1965.0.

Figs. 1 and 2 show the geoidal undulations and the geomagnetic secular variations respectively arising from the third and fourth harmonics. It is clear from the pattern that the two force fields are indeed correlated within the frequency range represented in the maps.

There are two explanations. (1) The long wavelength components ($n = 3$, 4) of the gravity field are associated with mass inhomogeneities in the core. (2) The sources for these components lie in the upper mantle, but their distribution is associated with geophysical parameters which affect the geomagnetic field also.

Mass anomalies in the core could be the result of either (*a*) geometrical distortion of the core–mantle boundary; or (*b*) lateral density variations in a geometrically level core–mantle interface.

Undulations of the core–mantle interface required to produce a given gravity harmonic are easily computed from formulas given by Cook[5] (Table 2, part *A*). The density differences can also be computed by a slight modification of the same formulas (Table 2, part *B*). Undulations need only be of the order of 1 to 2 km and the density difference of the order of 10^{-2} g/cm³ to produce the third and fourth harmonics in the geopotential.

This explanation, however, has important geophysical consequences which are not substantiated at present. First, if there is a differential rotation between the core and the mantle because of loose electromagnetic coupling between the two, the gravity contribution of the third and fourth harmonics will show a westward drift at about the same rate as the geomagnetic secular variations. If the north–south component of the drift is ignored, the drift will affect only the tesseral harmonic geopotential coefficients, but the time span and precision[9,14,15] of these measurements are not adequate. The only other geophysical data, pertinent to drift, are tidal records. Fig. 1 shows that, if there is a westward drift, sea level in certain areas will change by as much as 30 to 40 m over periods of 150 to 200 yr. There have been sporadic reports of long-period changes in sea level[16,17], but the tidal records do not give general evidence of changes of this periodicity and amplitude (our unpublished work).

Table 2. AMPLITUDES OF THE CORE–MANTLE BOUNDARY UNDULATIONS AND DENSITY ANOMALIES REQUIRED TO PRODUCE A GIVEN HARMONIC

A. Undulations

Degree of zonal harmonics (n)	Amplitude t_n* (km)
3	1·09
4	1·62
5	0·53

B. Density anomalies†

Degree of zonal harmonics (n)	Amplitude σ_n* (g/cm³)
for $t_n = 10$ km	
3	4×10^{-1}
4	6×10^{-1}
for $t_n = 100$ km	
3	4×10^{-2}
4	6×10^{-2}

* Let t_n denote the maximum amplitude of the undulation required to produce nth zonal harmonic coefficient C_n in the external potential of the Earth, then[5]

$$t_n = a_e \frac{2n+1}{3} \frac{\sigma}{\sigma_n} \left(\frac{a_e}{r_c}\right)^{n+2} C_n$$

where σ is the mean density of the Earth, σ_n, the anomalous density, r_c, the radius of the core, and a_e, the equatorial radius of the Earth. Note that the formula holds for $t_n \ll M_c$.

† Computed by slightly modifying the above formula for t_n.

Second, it is difficult to explain how these horizontal variations in the properties of the core–mantle boundary are maintained. The outer core is fluid and cannot support them. The only reasonable mechanism of support would be hydromagnetic (refs. 4 and 8 and our unpublished results), but the value of the toroidal magnetic field required will be about two orders of magnitude greater than the generally accepted value[8,18] at the core–mantle boundary.

We propose that the correlation is mainly due to the effect of lateral temperature variations in the upper mantle[19] on both of the force fields.

The gravity contribution of the third and fourth harmonics reaches a maximum of 15–20 mgals. To produce this gravity effect, an infinite slab of material with density contrasts of about 5×10^{-3} g/cm³ and 5×10^{-4} g/cm³ will have thicknesses of 100 km and 1,000 km, respectively. If thermal effects are responsible for producing this gravity effect, the lateral temperature anomalies in the upper mantle will be of the order of 10² °C. For most of the anomalous areas these values will be smaller.

If the surface heat flow accurately reflects the temperature distribution in the upper mantle, the maxima of heat flow should

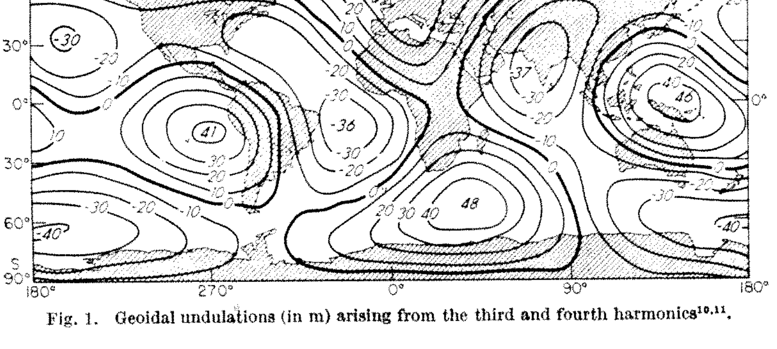

Fig. 1. Geoidal undulations (in m) arising from the third and fourth harmonics[10,11].

coincide with minima of the gravity field and vice versa. The existence of such a correlation is highly controversial[20–23]. The degree correlation function of gravity and heat flow is likely to provide a better insight into their relationship, but as yet there are not enough heat flow data. Moreover, there may be a time-lag due to low thermal conductivity of mantle material. In order to examine the thermal state of the upper mantle we have to depend on estimates of temperature distributions characteristic of different parts of the upper mantle.

Fig. 3 gives several temperature distributions[24] and shows that lateral temperature anomalies of considerable amplitude can exist in the upper mantle (assumed to be composed of olivine-rich peridotites). Fig. 4 shows that electrical conductivity of the upper mantle increases sharply with temperature[28,29]. The lateral temperature anomalies generate electrical conductivity anomalies, thus creating a spherical shell of variable electrical conductivity superimposed on a non-conducting or a uniformly conducting upper mantle (Fig. 5). The changing fields in the core induce stronger currents in the hotter and hence more conductive areas, and their associated magnetic fields oppose the propagation of the source magnetic field, thus attenuating[30] it as it passes through the shell. Hence the geomagnetic secular variations over hotter areas suffer more than normal "electromagnetic shielding". The reverse is true for colder areas. The net effect is that the gravity lows over the hotter upper mantle match geomagnetic isoporic lows and the gravity highs over the colder mantle match the isoporic highs.

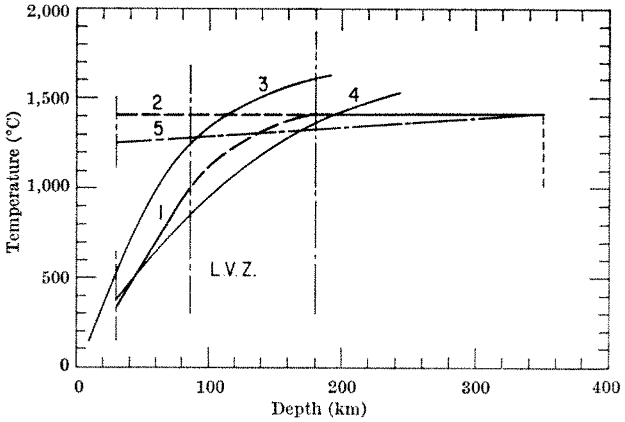

Fig. 3. Estimated characteristic temperature distributions[24] in different parts of the upper mantle. Curve 1 corresponds to temperature distribution in the thermally "normal" upper mantle based on Kanamori's[25] compressional wave velocity versus depth model for the tectonically active regions of the upper mantle and mineralogical considerations[24] governing the composition of the upper mantle. Curve 2 represents temperature distribution in the hotter upper mantle based on similar considerations. Curves 3 and 4 are representative temperature distributions in the upper mantle, under oceanic and shield areas respectively, as suggested by Ringwood[26]. Curve 5 corresponds to the adiabatic temperature distribution[27] calculated on the assumption that there is no partial melting in the low-velocity zone.

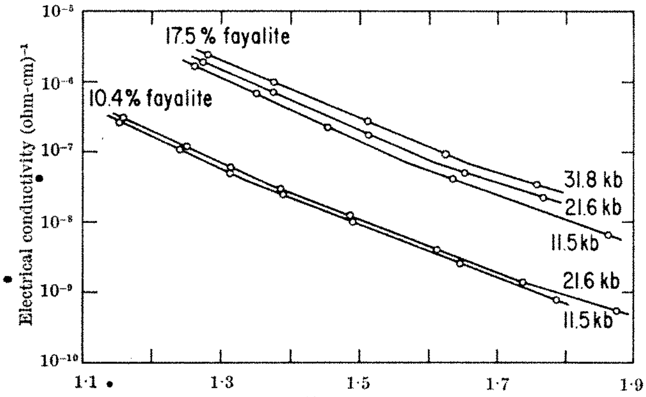

Fig. 4. Electrical conductivity of olivine as a function of temperature[29]. The mantle is assumed to be composed of olivine-rich peridotites so that the electrical conductivity of the mantle is effectively represented by that of olivine. It is also instructive to examine the theoretical dependence of the electrical conductivity σ on temperature which is given as

$$\sigma=\sigma_0\, e^{-A/T}$$

where σ_0 is a constant proportional to the number of ion-pairs per cubic centimetre, A is a constant identified with the excitation energy and the Boltzmann's constant and T is the absolute temperature.

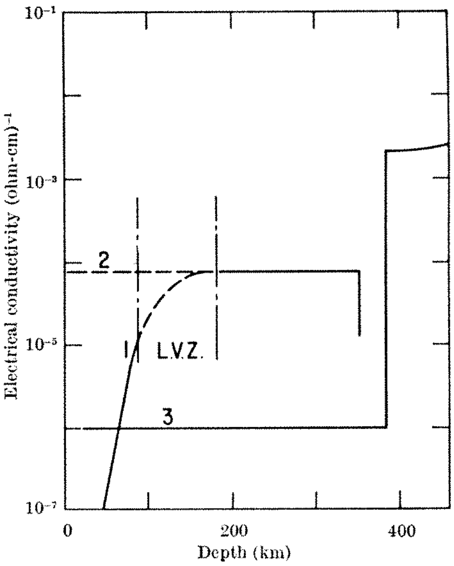

Fig. 5. Electrical conductivity distributions[24] in the upper mantle for some of the temperature distributions shown in Fig. 3. These distributions are estimated on the assumptions that: (i) the electrical conductivity data of olivine having an Fe : Mg ratio of 1 : 9, shown in Fig. 4, are representative of the olivine-rich peridotites which are generally assumed to constitute the mantle material; (ii) the pressure effects on the electrical conductivity are negligible; and (iii) the effect of partial melting on the conductivity can be ignored. Curves 1 and 2 show the electrical conductivity distribution for the temperature distributions given by curves 1 and 2 respectively in Fig. 3. Curve 3 corresponds to the electrical conductivity distribution suggested by Rikitake[18].

Recently, it was shown that the sources of the satellite-determined gravity anomalies lie in the asthenosphere[31]. It has also been shown that the positive gravity anomalies are generally associated with areas of deep-focus earthquakes, deep-sea trenches, and the young folded mountains[32,33]. Moberly and M. A. K.[34] have proposed a pattern of motions in the asthenosphere which explains the extremums of the gravity field. Considering the degree of harmonic representation used in Fig. 1 it shows good agreement with the pattern of "static", "filled-in" and "mobile" asthenosphere proposed by Moberly and M. A. K.[34]. This gives additional support to our theory that the thermal state of the upper mantle provides sources for the low-degree gravity harmonics as well as their correlation with the geomagnetic secular variations.

If the conductivity variations in the upper mantle are indeed damping the amplitudes of certain frequencies of the source magnetic field, the non-dipole field and its secular variations will be even more pronounced at the core–mantle boundary than has hitherto been suggested[35].

Earth Normal Modes from a 6·5 Magnitude Earthquake

THE Earth normal mode spectrum, between 8 and 39 cycles per hour (c.p.h.), has been obtained with a 20 dB signal-to-noise ratio for a relatively small earthquake ($M_s = 6·5$), using a low noise broad-band vertical accelerometer of new design. The earthquake occurred in the New Hebrides (18·9° S, 169·3° E) on October 13, 1969, 06 : 56 G.M.T. at a depth of 246 km.

The instrument used[1-2] has a bandwidth extending from tidal to seismic frequencies. It uses a quartz fibre in torsion, phase sensitive capacitance detection and electrostatic feedback[3]. The internal instrumental noise was measured in the band 1–30 c.p.h. by cross-correlating[2] with another similar instrument, and was found to be the calculated Brownian noise of 2×10^{-24} g²/c.p.h. Instrumental drift is so small ($< 10^{-9}$ g/day) that it can be operated at full scale tidal gain for several months without re-zeroing.

The instrument has two outputs at present. The tidal output (Fig. 1) is flat from DC to 5·75 c.p.h., where it breaks at 20 dB/decade. The gain in the tidal channel is such that ±10 V output, or full scale, corresponds to $\pm 3·7 \times 10^{-7}$ g. The second output is a band pass filter with 40 dB gain relative to the tidal channel in a 1–30 c.p.h. band. Above 30 c.p.h. the filter output drops off at 40 dB/decade. The filter gain is such that ±10 V corresponds to $\pm 3·7 \times 10^{-9}$ g in the 1–30 c.p.h. passband. The calibration factor[4] for the instrument was obtained from a static tilt calibration using the tidal data channel and correcting for the added gain of the filter channel in the 1–30 c.p.h. passband.

The site, near Miramar Naval Air Station in San Diego, is noisy at seismic frequencies from jet engine noise, but at Earth mode frequencies (1–30 c.p.h.) the ambient power spectrum (Figs. 3 and 4) is low enough to permit the measurement of normal mode frequencies and line structure from small earthquakes.

Tidal data for a two day run are shown in Fig. 1. These are raw data which have been analogue filtered by a two-stage buffered RC filter with a 100 s time constant and digitized at 1 s intervals. The earthquake (Fig. 2) shows up as a symmetric trace superimposed on the band pass filter record, and showing the absence of nonlinear mechanical coupling within the instrument. Figs. 3 and 4 show the earthquake power spectrum from 1 to 39 c.p.h. The typical ambient power spectrum of the site was obtained from filter data corresponding to the 15 h time period AB (Fig. 1). The earthquake power spectrum was obtained from the filter data corresponding to the 15 h period CD. A small underseas earthquake occurred in the period BC, which could not be used to obtain an ambient power spectrum.

A comparison of the measured modal spectrum with the ambient power spectrum shows that there are several low order modes which can be distinguished[4] from the noise below 10 c.p.h., and that the mode structure above this frequency is real. In fact, in the region from 10 to 39 c.p.h., the signal-to-noise ratio is better than 20 dB.

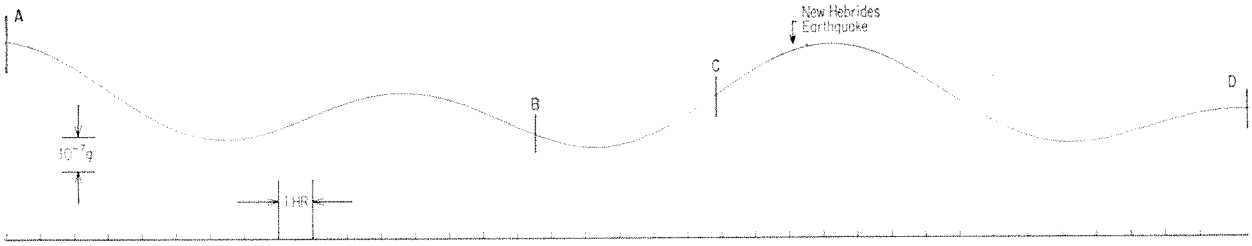

Fig. 1. Tidal channel output from 8:29:17 GMT, October 12, to 20:58:36 GMT, October 13. Filter channel output corresponding to tidal data from Section AB was used to obtain the ambient spectrum for the site. The main earthquake time series was taken from the filter channel output corresponding to section CD.

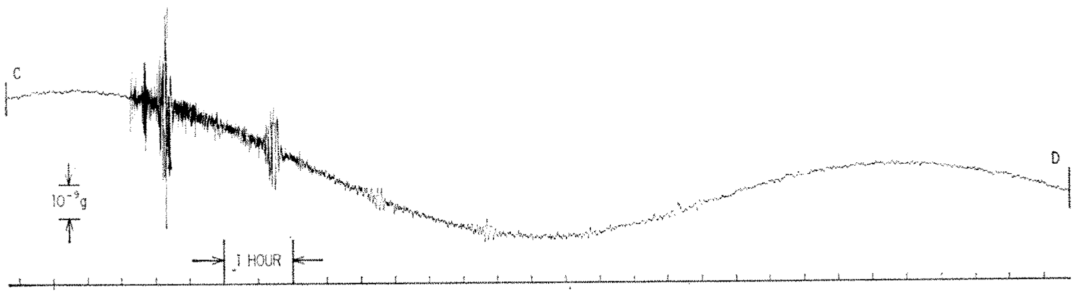

Fig. 2. Raw filter channel output corresponding to section CD of Fig. 1, showing the details of the time series for the New Hebrides earthquake.

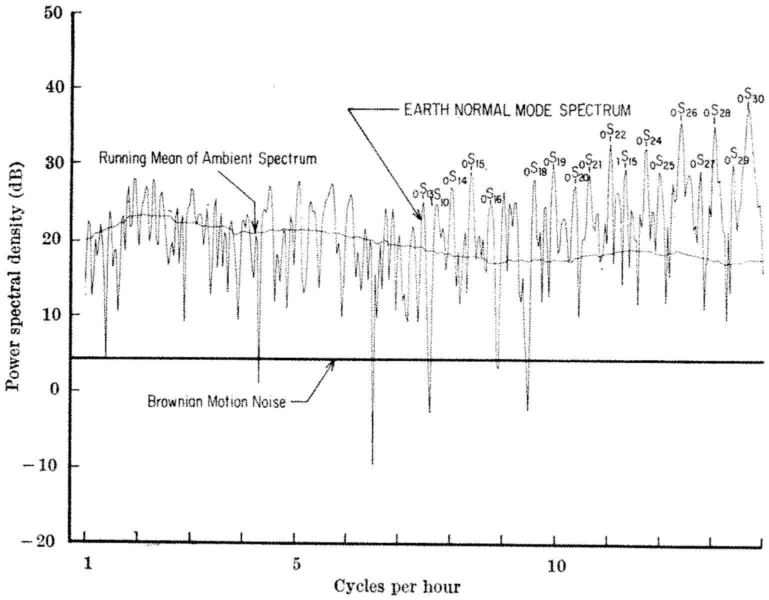

Fig. 3. Spectra from 1 to 14 c.p.h. The Earth normal mode spectrum refers to section CD in Figs. 1 and 2. The running mean of the ambient spectrum refers to section AB in Fig. 1. Brownian motion noise is shown as the heavy solid line. The 0 dB point corresponds to an absolute spectral density of $7\cdot4\times10^{-25}$ g²/c.p.h. Selected modes are identified (personal communication from Freeman Gilbert and ref. 5).

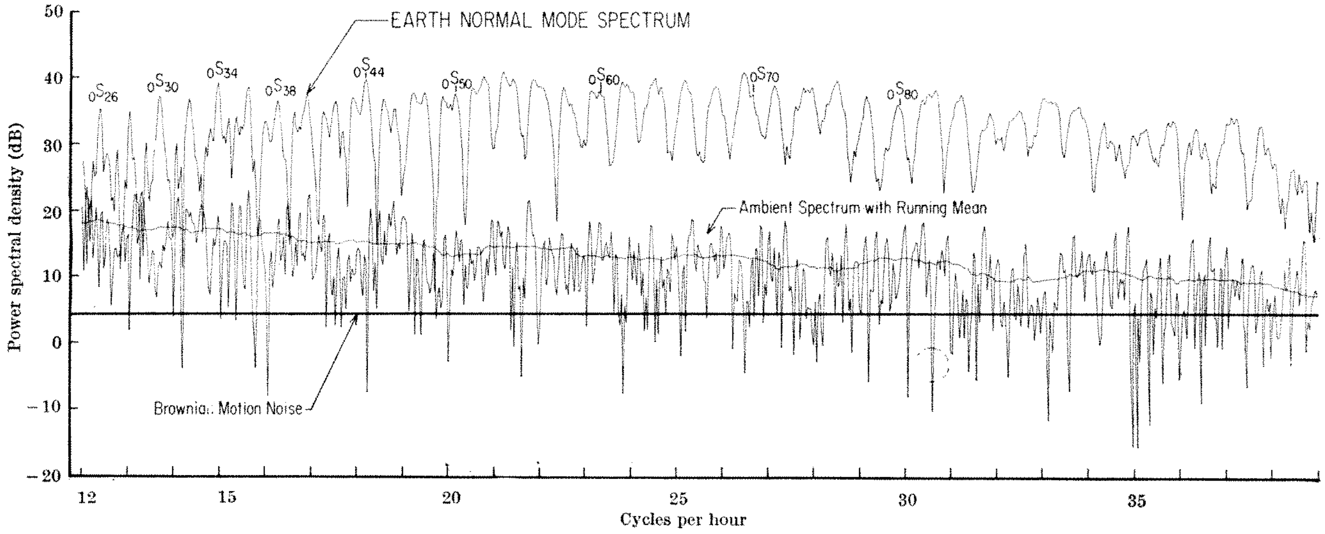

Fig. 4. Spectra from 12 to 39 c.p.h. The Earth normal mode spectrum refers to section CD in Figs. 1 and 2. The ambient spectrum and its running mean refer to section AB in Fig. 1. Brownian motion noise is shown as the heavy solid line. The 0 dB point corresponds to an absolute spectral density of $7\cdot4\times10^{-25}$ g²/c.p.h. Selected modes are identified (personal communication from Freeman Gilbert and ref. 5).

Although not shown in the figures, spectra for both the earthquake and the ambient noise were taken up to a frequency of 120 c.p.h. Up to this frequency, the earthquake spectrum shows considerable structure at least 20 dB above the ambient spectrum. At a more favourable site, the ambient noise would be lower and would enable data to be gathered over a longer time for increased mode resolution. For this reason, instruments which have a considerably lower Brownian motion limit than the one used here are under construction.

The good signal-to-noise ratio (20 dB) found here shows that normal mode and earthquake source data can now be obtained for a much larger class of earthquakes than previously possible. The smaller earthquakes can be examined for source structure and the large ones, with their consequently longer data runs, can be used to resolve modal line structure. A more complete treatment analysing several earthquakes is in preparation.

We thank James Brune for his help in identifying various features of the earthquake, Richard Haubrich for his assistance in the data handling and analysis and Freeman Gilbert for his assistance in identifying normal modes. This research was supported by the Advanced Research Projects Agency of the Department of Defense and was monitored by the Air Force Office of Scientific Research.

Diamond Accumulation in the Upper Mantle

THE present high gradient of density in the upper mantle provides neutral buoyancy zones in which certain minerals may have been accumulated in the past or to which they may still be migrating. The necessary condition for progressive accumulation in such a zone is that the mineral concerned has opportunities of rising or sinking relative to its surroundings with a velocity which, averaged over long periods, is great enough to overcome the bulk convective drift if such occurs. Frank[1] has pointed out the high heat transfer capability of a small volume fraction of melt fluid percolating through the bulk, compared with bulk convection. With percolation active, it is likely that a fluctuating distribution of migration and local concentration of fluid has been the dominating pattern of events in the mantle, at least down to 500 km, during a large fraction of the Earth's history. Hence it is unlikely that any portion of the mantle above this level has escaped epochs during which fluid has percolated through it. If during such an epoch of involvement in local fluidity the fluid fraction becomes sufficient to lower the effective viscosity to within an order of magnitude of that of a normal homogeneous melt, then insoluble crystals suspended in the partial melt, rising or falling under buoyancy forces, could well attain velocities a million-fold greater than any plausible bulk convection velocity of the mantle in which the localized partial melt is embedded.

Table 1. DIAMONDS IN THE UPPER MANTLE

(i) Depth (km)	(ii) Pressure (kbar)	(iii) Mantle density ϱ_M (g cm^{-3})	(iv) Diamond density less mantle density $\varrho_D-\varrho_{M_3}$ (g cm^{-3})	(v) Viscosity velocity product ηv (dyne cm^{-1})
100	33	3·32	0·18	2·2
200	65	3·35	0·16	2·0
300	98	3·44	0·08	1·0
400	130	3·62	−0·09	−1·1
500	170	3·89	−0·34	−4·3
600	210	4·14	−0·57	−7·2

Consider diamond, for if migration towards a neutral buoyancy zone has acted to concentrate any mineral at all, then it would be expected to have operated on this species. Diamond is the physically stable form of carbon from a depth of about 100 km down to 1,200 km or more[2,3] and its neutral buoyancy level, as shown by Table 1, is at about 350 km depth. In Table 1, columns (ii) and (iii) give the pressure and mean mantle density at the depth stated in column (i) according to Solution II of Birch[4] which is close to Bullen's *A*(*i*) model[5]. Column (iv), which lists the difference between the density of diamond (ρ_D) and mantle (ρ_M), makes use of Berman's calculations of the density of diamond at zero pressure and elevated temperature[2] together with the value $1{\cdot}75\times10^{-4}$ kbar^{-1} as the compressibility of diamond. The variation of temperature with depth adopted is the mean of the "oceanic" and "continental shield" distributions of Tozer[6]; it suggests about 1,900 K at the neutral buoyancy depth of 350 km. The final column (v) is based on special assumptions. It takes a typical diamond to be one having a volume of 0·1 cm^3, or a mass of 0·35 g ($1\frac{3}{4}$ carats), and to be of octahedral shape. The distance from centre to corner of the octahedron is used as the effective particle radius in the Stokes formula for drift velocity v cm s^{-1} through a medium of viscosity η poise.

It will be seen that velocities of drift towards the 350 km level exceed 1 km yr^{-1} at distances greater than 50 km above or below this level when the viscosity is 300 poise or less. If a diamond of the size assumed becomes but once in every 10^6 yr incorporated for a brief period in a local accumulation of partial melt extending vertically through a depth of order 1 km, then the aggregate of possible vertical drifts would be sufficient to produce, say, a descent from 100 km to 250 km in about 10^8 yr.

Does any evidence point to the existence of a diamond reservoir at a depth of 350 km? Very long storage at about 1,900 K would probably provide good conditions for developing the distribution of nitrogen impurity platelet precipitate commonly observed in diamond, but much shorter exposures to high temperature (such as would be experienced in a rapidly rising and expanding melt) might be sufficient[7,8]. Rather, perhaps, one should enquire where does the Earth's store of carbon reside? In meteorites and in the Earth's lithosphere there is about one carbon atom to every 300 silicon atoms[9]. But the majority of meteorites seem to have been derived from small bodies in which negligible internal pressures due to gravity would have been developed, and much carbon may have escaped as volatiles. In bodies the size of the Moon and greater, interior pressures rise well into the diamond-stable region of the carbon phase diagram, making possible the retention of carbon as dense and unreactive diamond. Allowing the Earth's mantle no greater abundance of carbon than has been retained by meteorites, and assuming such carbon to be principally in the form of diamond, then if most of the diamond has migrated to within 100 km of its neutral buoyancy level, diamond concentrations in this zone might exceed one per cent.

Fitting, Fretting and Imprisoned Boulders

THE occurrence on rocky coasts of what Shelley[1] aptly calls "fitting boulders" is, as he says, not mentioned in standard works on shore processes; but the late Professor J. A. Bartrum discussed such boulders with me in 1934 and used the term "fretting" in relation to the development of common interfaces between adjacent boulders. Baker[2] described an example near Cape Paterson in Victoria (Australia) using the term "imprisoned rocks", and indeed they are not uncommon on the Victorian coast. I have observed them at Beaumaris among blocks of soft red Tertiary sandstone derived from collapses of the cliff face, also at Sorrento in Pleistocene calcareous aeolianite, and again around Lorne and Cape Paterson where the rocks are Mesozoic arkoses. They occur also at St David's (South Wales). Shelley's descriptions afford a basis for comparison.

Among the New Zealand examples one type comprises agglomerations of boulders piled together and fitting closely, the other being large isolated boulders which fit against the bedrock base. This is also true in Victoria. In both areas fitting boulders lie about or above mean sea level, but certainly in Victoria in a zone which is at present subject to wave action if only during storms. Shore platforms, on which the boulders occur as large isolated blocks

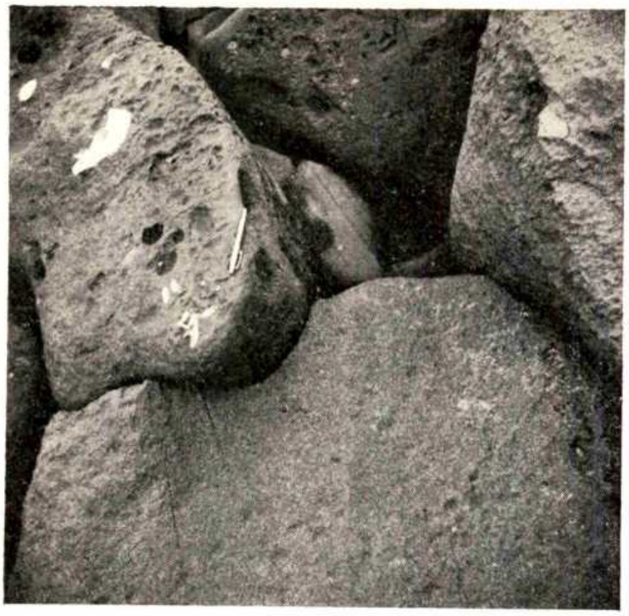

Fig. 1. Fitting boulders of Mesozoic arkose at base of cliff, Point Castries, Victoria. Blocks are derived from roadworks on hill above.

or piled against the cliff base, are normally free of boulders or cobbles, and it was the unusual sight of a shore platform dotted over with blocks of rock up to some 2 cubic yards in size that led me to investigate the matter. At Point Castries near Lorne roadworks had been carried out, and large volumes of broken rock (arkose and mudstone) had been recently dumped onto the shore platform. The finer grades or rubble had already been washed away leaving only the largest blocks scattered on the platform, and a residual pile aligned along the base of the cliff including blocks of all sizes from 3–4 feet down to a few inches across, the blocks resting as described by Shelley and by Baker intimately against each other with closely fitting interfaces (Fig. 1). At the base the shore platform had been eroded to a depth of an inch or two, forming a gutter beneath the boulder pile, which later at first sight resembled a storm beach except for the complete disarray of the blocks, their lack of sorting, and, of course, their environment. Indeed, those blocks that had not become interlocked had been swept away. It seems that the final action of waves of translation that cross shore platforms is to induce repeated small jigging and jogging movements among such boulders, causing them to fret against each other and against the base on which they rest.

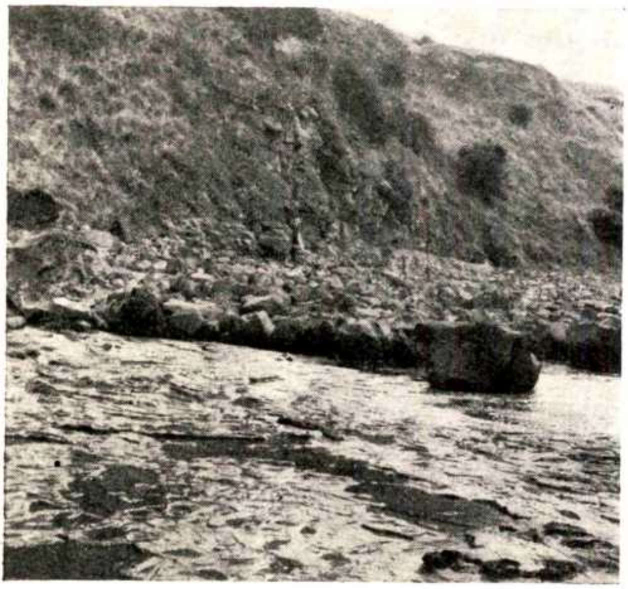

Fig. 2. Shore platform in arkose near Cape Paterson, Victoria, with a partial cover of fretting boulders derived from cliff collapse outside the photographed sector, behind the observer. Longshore drift from left to right.

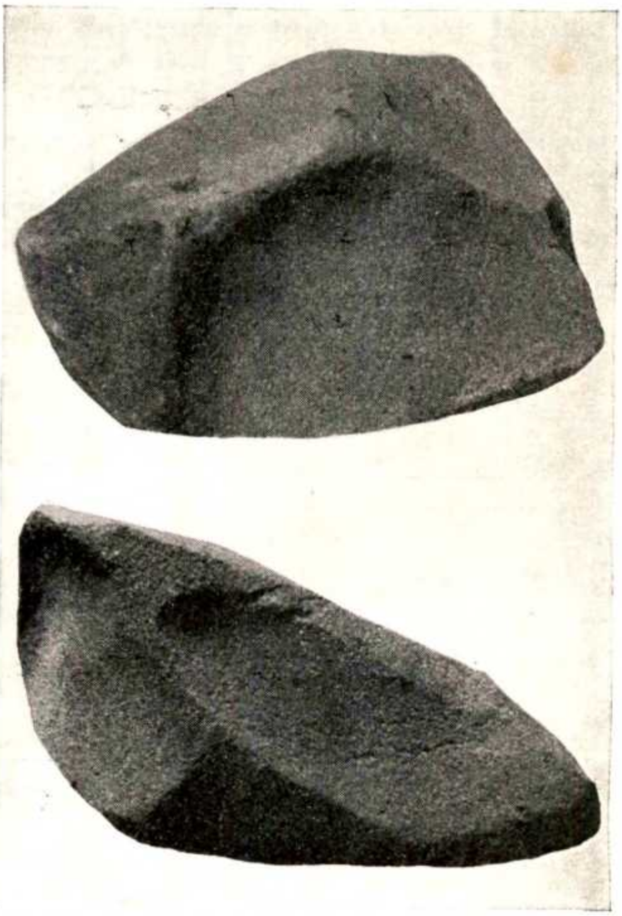

Fig. 3. Imprisoned boulders, each about 8 inches in length, removed from within a pile of fitting arkose boulders, Point Castries.

The conditions at Cape Paterson are similar, but there it is massive collapses of the cliff face that have supplied the debris. While the shore platform has been stripped bare in exposed situations, hundreds of blocks averaging about 2·5 cubic feet have been lifted and pushed along it towards the leeward end until they completely cover the platform and the wave ramp with a layer one block deep, all jostling against each other (Fig. 2). It is clear that to the limit of their capacity, waves remove such debris. Only in the gutter previously mentioned or locally beneath large residual blocks is the platform in any way affected, the removal being either rapid or completely resisted.

At all localities studied in Victoria[3] the fitting boulders originated from some special cause, which is not directly related to the processes involved in the formation of level shore platforms. In most instances the blocks derived from collapse of the cliff face. Although the undermining of cliffs results from marine processes, collapses are episodic and the sudden addition of great quantities of debris is a catastrophic event unrelated to the balance of erosion and transportation on the strand. Thus the situation with cliff falls is comparable with that of the artificial dumping of rocks at Point Castries.

Near Inverloch east of Cape Paterson, at a place called the Sheep Rocks, there is a low cliff which does not provide rock falls. The platform is, however, dotted over with large ellipsoidal blocks, some of which remain supported as mushroom rocks, others becoming detached and fretting against the bedrock base. These blocks are concretionary nodules in mudstone and arkose, released by weathering and erosion on the platform, and accordingly they are a capricious result of the marine processes that are involved in the development of a platform in the host rocks. The example at Lake Wanaka reported by Shelley, where boulders of chlorite-zone schist are derived from moraines, is comparable in that the waves on the shore are presented with ready made boulders which they themselves did not produce.

I disagree with Shelley's suggestion that crystallization of salt (or ice) is the principal agent involved in producing fitting boulders (Fig. 3). It is optically demonstrable that the boulders are moved by wave action, and the notion that long-continued very small movements are indeed responsible is inescapable. There is in Victoria, moreover, a relationship between wave force and the maximum size of fitting boulders, also with the height above mean level at which fitting boulders are to be found. This ranges from 3 to 4 feet in relatively sheltered and shallow waters of Port Phillip Bay to more than 10 feet on the exposed southern coast. One block 15 × 10 × 10 feet is fitted to the shore platform at mean sea level at Sorrento and salt crystallization is impossible for this and many other examples which never dry out. Ice formation on the shore is unknown in Victoria.

The most significant inference to be drawn from occurrences of fitting boulders is that the development of level shore platforms is not due to abrasion by waves armed with pebbles and boulders, but to other processes operating within the broad zone subject to wave attack on cliffy coasts.

Buried Channels of the Thames Estuary

As part of a detailed and continuing study of the distribution and movements of the sediments in the area of the Thames Estuary shown in Fig. 1, we have tried to discover the thickness of the superficial deposits overlying the bedrock which is London clay for the greater part of the estuary.

More than 350 nautical miles of continuous reflexion seismic profiling from the MFV Sea Symphony were run during 1967–68 with an additional 120 nautical miles during 1969. Profile records from a further 300 miles were made available to us by kind permission of Marinex Gavel Ltd.

Equipment used in 1967–68 and for the Marinex records was a Hunting Hydrosonde 2A sparker system used at 165 J energy level. In 1969 a modified Edgerton Germeshausen and Grier sparker system was used at varying energy levels, mostly 100 and 200 J. Navigation and

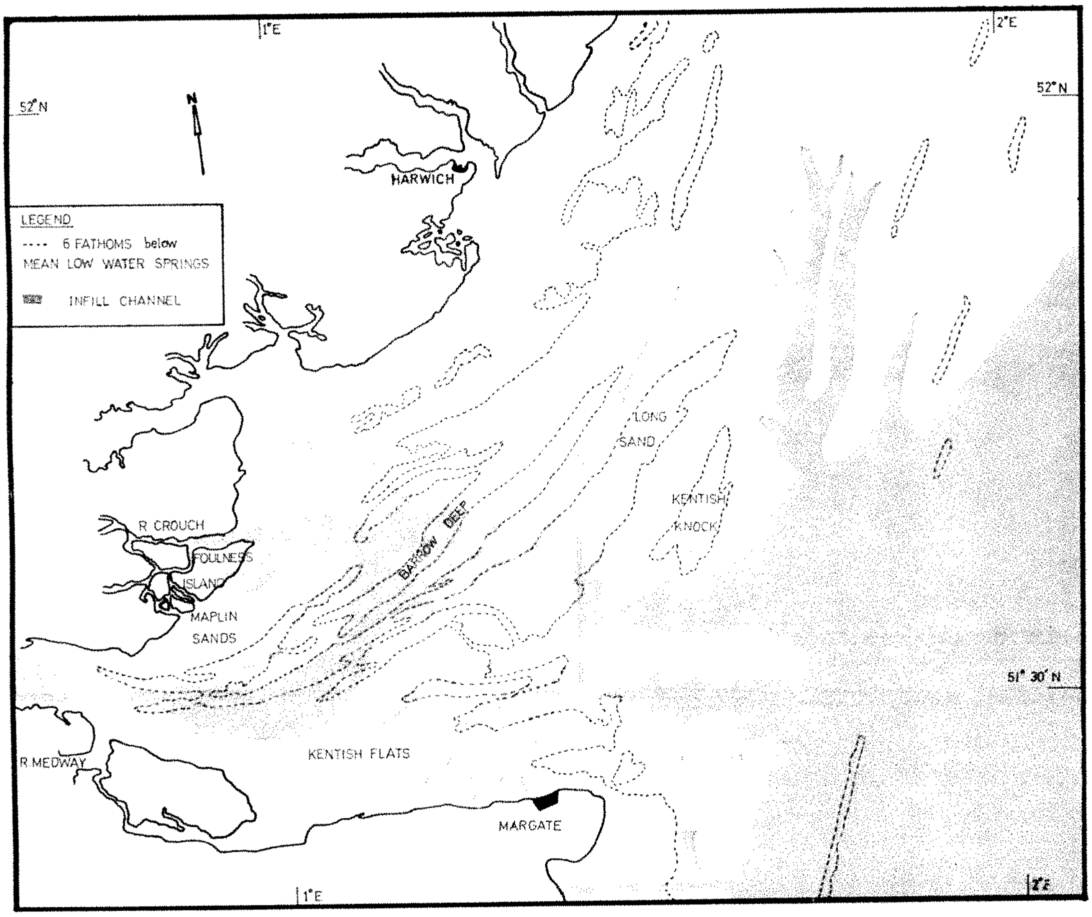

Fig. 1. The present configuration of the Thames Estuary and its main buried channels.

position fixing throughout the surveys were by Decca Navigator Mark 12. Additional information came from some deep boreholes and by using a (Shell) gravity corer in critical areas. Many hundreds of seabed samples and more than 200 miles of Kelvin Hughes MS 43 Transit Sonar records have also proved very useful.

The thickness of superficial sediment varies in the estuary from nothing or only a few inches of sand, shell or gravel to a maximum of approximately 160 feet. Much of this sediment is contained in large linear sandbanks which trend south-west–north-east, while an equal or perhaps even greater quantity infills a series of deep channels cut into the surface of the London clay and, in the extreme south around the Isle of Thanet, the chalk. The possible relationships between the present sandbank and channel topography and the buried channels have been reviewed before. It is only now that modern techniques have enabled a relationship to be established[1].

A preliminary description of these channels cut at a time when sea level was at least 200 feet lower than at present is given here; a detailed analysis of all the evidence is nearing completion and will be published later.

The main buried channel runs due east, meeting the buried channel of the River Medway in the region of the Spile Bank. This channel, now wider and deeper, continues to run east before turning almost due north under Shivering Sands. After running for about five miles in a northerly direction it meets a complex of buried river channels, the precursors of the rivers now draining south-east Essex. The largest of these, the Crouch Channel, is more than 110 feet deep under Foulness Sands and merges there with a channel which it is believed (from borehole evidence) runs across Foulness Island and then turns to run north-east across the area now occupied by the Foulness Sands.

The confluence of the main Thames buried channel and the channels of the Crouch and its tributaries occurs in the vicinity of the Barrow Sand and Barrow Deep and this channel then runs in a direction south of east under Long Sand into an area south of the Kentish Knock sandbank before turning due east. South of this, once draining the area now occupied by the Kentish Flats and the mainly submerged outcrop of the chalk of Thanet is a channel running east the tributaries of which can be largely equated with those rivers and streams at present draining this area of East Kent.

Near the Inner Gabbard and Galloper sandbanks run channels draining south which are the subject of a detailed study at the moment and seem to have a complex history.

Precipitation of Metastable Carbonate Phases from Seawater

Because of the widespread occurrence of carbonates in marine sediments there has been a continuing interest in the mineralogy of carbonate phases that can be chemically precipitated from seawater[1-9]. The discovery of metastable carbonate minerals (aragonite and high-magnesium calcites) of non-skeletal origin occurring as cementing material in submarine sedimentary environments[10-12] has further stimulated interest in mechanisms that might explain these occurrences. Aragonites have been formed from seawater in a variety of experiments approximating natural conditions[7,8,13]. Attempts at the synthesis of high-magnesium calcites in such conditions have met with little success. We only know of three published papers in which high-magnesium calcites have been precipitated from seawater[2,5,9]. In only one of these was supporting X-ray diffraction evidence presented to document the mineralogy and in all cases the phases were produced by the addition of Na_2CO_3 or $NaHCO_3$.

The present work describes preliminary experiments involving precipitation of some metastable carbonates from seawater at room temperature using ammonium carbonate generated by a vapour diffusion technique[14], or by its *in situ* production through the enzymatic decomposition of urea with urease[15]. Because ammonium carbonate can be a natural by-product of biological activity, this suggests a mechanism by which such mineral phases might occur locally in marine conditions.

Seawater obtained from Woods Hole, Massachusetts (35 parts per thousand salinity), and at a station off the coast of Virginia (33 parts per thousand salinity) was filtered or allowed to settle. All experiments were run at room temperatures (23°–25° C) for durations of from 24 to 72 h. The precipitates were separated by filtration, washed with deionized water and dried with acetone. The dried precipitates were gently ground and examined using Debye–Scherrer X-ray diffraction powder techniques. Magnesium content of the calcitic material was estimated from the shift in the (112) reflexion[16].

To form precipitates through the vapour phase diffusion technique, 50 ml. beakers containing seawater were placed in a desiccator over solid ammonium carbonate. In seemingly identical conditions, precipitates formed from the vapour diffusion method included X-ray amorphous phases, monohydrocalcite ($CaCO_3 \cdot H_2O$), a mixture of nesquehonite ($MgCO_3 \cdot 3H_2O$) and aragonite, and magnesian calcites ranging in magnesium content from 3 to 32 mol. per cent $MgCO_3$. The high-magnesium calcites occur as very finely divided powders consisting of individual or interpenetrating wheat-shaped crystals (Fig. 1). The experimental data are summarized in Table 1.

Table 1. SUMMARY OF DATA ON CARBONATES PRODUCED FROM SEAWATER

Sample	Seawater salinity (parts per thousand)	$(NH_4)_2CO_3$ procedure	Phase precipitated	Calcite* Δd_{112}	Mol. per cent $MgCO_3$
1	33	Vapour	Transition	—	—
2	33	Vapour	Transition (recryst. aragonite + nesquehonite)	—	—
3	33	Vapour	Monohydrocalcite	—	—
4	33	Vapour	Calcite	0·076	27

15	35	Enzyme	Aragonite + calcite	0·048	17
16	35	Enzyme	Aragonite + calcite	0·033	12

* Although incorporation of other cations is possible, the shift in the (112) reflexion here is considered to be entirely due to magnesium.

In the cases where nesquehonite and aragonite formed, a transition phase was commonly observed. This phase consisted of radiating clusters of sharply terminating, clear crystals. The crystals were soluble in distilled water and recrystallized in seawater or the mother liquor to nesquehonite and aragonite. Comparison of the measured *d*-spacings of this transition phase from seawater with those of the phase produced in the same manner from a 0·6 M solution of $MgCl_2 \cdot 6H_2O$ shows them to be very nearly similar (Table 2). If allowed to dry, it eventually becomes opaque

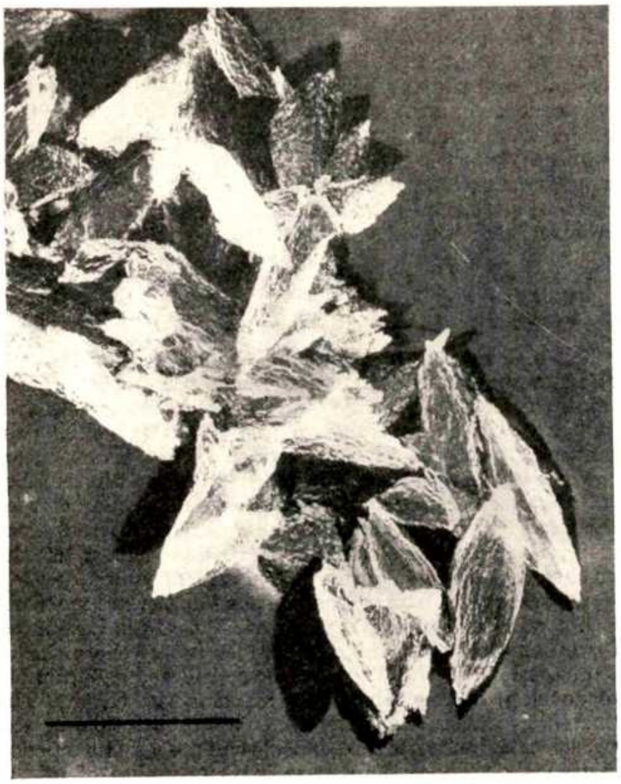

Fig. 1. Electron micrograph of magnesian calcite (9 mol. per cent $MgCO_3$) formed by vapour diffusion of $(NH_4)_2CO_3$ in seawater. Scale represents one micron.

and amorphous to X-rays. X-ray examination of calcined samples of the crystals showed strong lines for MgO and weak lines for CaO. The addition of ammonium carbonate to magnesium solutions is a common method of preparing ammonium magnesium carbonate[17], $(NH_4)_2CO_3 \cdot MgCO_3 \cdot 4H_2O$. Although we have found no published X-ray data for this compound, the physical properties together with our X-ray data suggest an impure, calcium-rich, ammonium magnesium carbonate. The presence of the larger calcium ion would account for the slightly larger *d*-spacings observed in the seawater precipitate.

In order to study precipitates involving the *in situ* enzymatic production of ammonium carbonate, 1·0 g of urea and 0·1 g of urease were allowed to react in stoppered flasks containing 100 ml. of seawater. Here the precipitates include monohydrocalcite and mixtures of aragonite and high-magnesium calcites as well as X-ray amorphous material. The magnesium content of the calcites ranged from 12 to 22 mol. per cent $MgCO_3$ and the data are included in Table 1. In no case was nesquehonite or the transition phase observed, probably because of lower concentrations of ammonium carbonate.

Earlier work with precipitates[2,5] produced by the addition of sodium carbonate to seawater indicates that the concentration of Na_2CO_3 and the *p*H of the solution at the time of nucleation are important factors controlling the phases produced. Similarly, in the present experiments, the amount of ammonium carbonate added by diffusion or enzyme action and the *p*H of the seawater at the time the precipitate forms may determine the type of carbonate produced. Furthermore, particulate material not removed by settling or filtering may have acted as seeds and influenced the final products. Additional work should indicate the degree to which these processes may be operational in the local submarine environment where metastable carbonates of non-skeletal origin are now observed.

Polymer Microdefects as the Centres of Destructive Cracks induced by Laser Irradiation

UNDER laser radiation separately located disk-shaped cracks are formed in irradiated transparent dielectrics such as polymethylmethacrylate (PMMA), polystyrene (PS) and polycarbonate (PC). To explain this for materials with small absorption coefficients the sample must have particular sorts of microdefects and we now consider the size, location, structure and properties of these microdefects.

The cleaving effect of the gas is the cause of these destructive cracks[1,2]. Uniform compression of the sample can obviously prevent the crack development, and the further from the focal points of the irradiation the less probable is the formation of a crack. Uniform compression will first of all prevent the formation of remote cracks, as shown by experiment[3]. From the results of these experiments it is possible to determine the minimum gas pressure (180 ± 10 atmospheres) in microdefects required to cleave the sample and lead to the formation of cracks. It is possible to determine the maximum initial size of a microcrack which is about 10^{-4} cm[1], from the dependence of the gas pressure in a crack on its radius. Hence, the sizes of microdefects, in which the gas which cleaves the

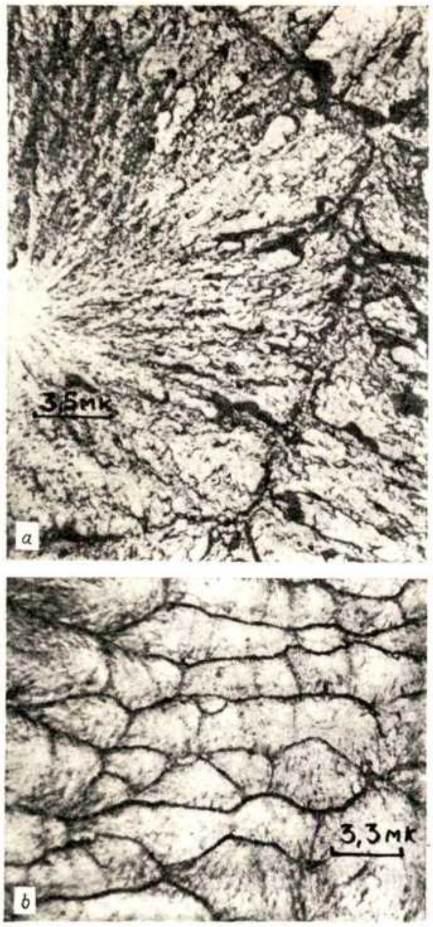

Fig. 1. Microstructure of block, amorphous PMMA (unirradiated sample). *a*, Large domain structure; *b*, small domain structure.

sample is formed, are not greater than 10^{-4} cm (PMMA and PS).

The location of microdefects can be determined by considering the relation between the microstructure and the destructions appearing in a polymer. The microstructures of amorphous polymers PMMA, PS and PC are essentially different. The microstructure of PMMA is characterized by domains, that of PS with batches of molecules rolled up into globules, and that of PC with batches of molecules combined into fibrillae located in the intersecting planes[4]. All of them, however, have one common feature—a great number of micropores (of linear dimensions up to 1 micron), which increase in number on stretching the sample[5]. PC has the greatest porosity. Fig. 1 shows the microstructure of two PMMA samples which differ in the domain diameters only. The corresponding destructions after the laser irradiation are shown in Fig. 2. The number of destructive cracks noticeably increases with a decrease in the average domain diameter. It may then be expected that the initiating microdefect nuclei are localized along the domain boundaries, where most of the PMMA micropores are situated. In equal conditions the number of destructions for PC is considerably greater than that for PMMA and PS (the porosity of polycarbonate is higher).

In the case of polycarbonate (PC) at 20° C, polymer structures become oriented in the vicinity of the developing cracks; this results in the localization of cracks. Because of this, the final size of the destructive cracks in PC is much less than that in PMMA or in PS, where there is no such localization. At −190° C localization does not occur, PC becomes fragile and its destruction differs from that of PMMA or PS only in the greater number of cracks present. Thus the sizes of the initiating microdefects coincide with those of the polymer micropores. They are located where most of the micropores are situated, and the number of destructions, in other words, the number of initiating microdefects, is higher the greater the number of micropores in the sample. We can therefore suppose that the microdefects are the micropores of polymer samples. This assumption can be checked by creating additional microdefect micropores in the sample by stretching it[5].

Table 1

σ (kg/cm^2)	0	100	200	300
n (cm^{-1})	11 ± 2	27 ± 3	36 ± 3	44 ± 6

Table 1 shows the value of the stretching stress σ and the number of destructive cracks per cm (n). These results indicate that the number of destructive cracks increases with the number of micropores (which is proportional to σ). The relation between σ and n is non-linear, because of the non-linear dependence of σ on the number of micropores appearing[5] and the random character of the process of crack formation under laser irradiation. Here, the external stretching force does not affect the mechanism of crack development and does not develop those cracks, where the gas pressure in the microdefects is not sufficient to make them visible. It is accounted for by the fact that the microcracks are of the order of 1 micron long so that they can be considered safe (unable to develop) at the values of σ listed in the table[6]. The stretching affects only the plane of orientation of the cracks and increases the initial volume of the opened micropores. Thus an increase in the number of micropores leads to an increase in the number of destructive cracks; in other words the destructive cracks are originated at polymer micropores.

Of course, not every micropore develops to the size of a destructive crack under the action of laser irradiation; some of them open up just slightly and can develop to visible sizes on subsequent irradiation[7]. It was proved experimentally[7] that during repeated irradiation destructive cracks appeared at those places where they were absent before, namely, at the points where micropores were opened by the previous laser pulses. The distribution of such opened micropores (as well as the destructive cracks) is not uniform, even in the same cross-section of the sample; this was proved by the method of light dispersion at these pores, and is probably due to the statistical

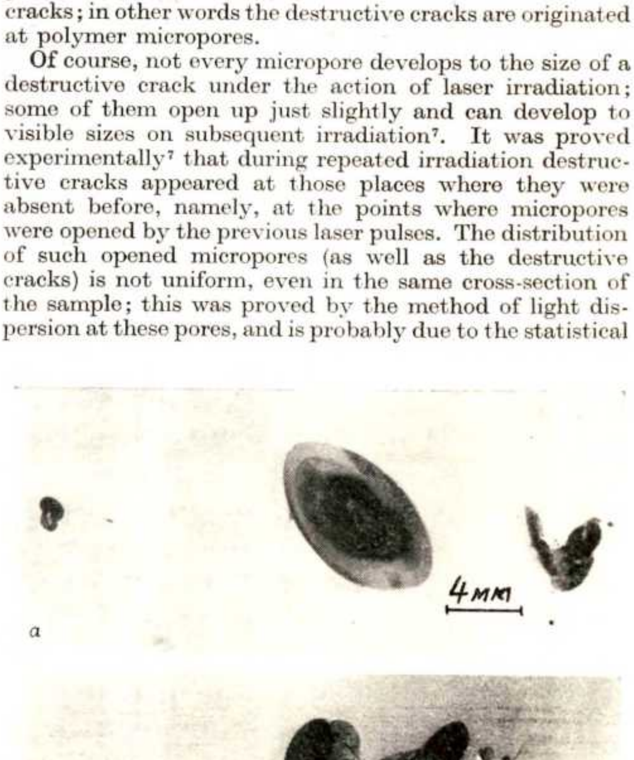

Fig. 2. Destructions in samples, subjected to laser irradiation, with large domain (*a*) and small domain (*b*) microstructure. Conditions in both cases are identical.

laws of crack formation under the effect of laser irradiation.

Thus all these experimental results suggest that the microdefect nuclei are micropores of materials such as PMMA, PS and PC.

A "Dust Curtain" in Gaseous Core Nuclear Reactors for Rockets

The use of nuclear, rather than chemical, energy for the propulsion of space vehicles would greatly extend the possibilities of space travel, and in recent years much progress has been made towards the realization of nuclear propulsion devices. The principle of rocket propulsion rests on the production of a highly heated working fluid, called the propellant gas, which is expanded and ejected through a nozzle, thereby converting its thermal energy to directed kinetic energy. The heating of the propellant can be derived from the reaction of combustibles with a chemical system, or, in the nuclear system, from the nuclear reaction of fissile materials. In the nuclear reactor the fissile material is the fuel, and the thermal energy released by fission is transferred to the propellant, usually hydrogen. This energy transfer can be achieved by the use of a solid core which serves as an intermediate medium for the energy delivery to the propellant. Although the solid core reactor has reached a prototype engine demonstration after a decade of development[1], it does not, however, make the optimum use of the nuclear energy in a rocket engine. This stems from the fact that fission energy is released at very high level (10^6 eV or 10^{10} K) which has been degraded in a solid core reactor to 3,000 K, the limit of the operational temperature of a solid core heat exchanger. It is therefore desirable to use a gaseous core in which the fuel, namely the highly energetic fission particles, and the propellant are intimately mixed, thus transferring energy directly via collisions and radiation.

The difficulty of constructing a gaseous core reactor lies in providing a specific flow field for the mixture in the reactor cavity which fulfils the criticality condition for nuclear chain reaction and at the same time minimizes the loss of fuel to the exhaust and of energy to the cavity wall.

A novel concept of gaseous vortex reactor was proposed by Kerrebrock and Meghreblian[2] in which the gaseous mixture sustains a vortex flow which results in a peaked concentration of the fuel at an appropriate radial distance from the axis of a cylindrical cavity, with very small concentrations at the cavity wall and on the axis. In other words, the containment of the fuel, or fuel suspension in the cavity, is achieved by taking advantage of the balance between the differential centrifugal force and the diffusional drag of the fuel against the radially inward flowing propellant. Conceptually the propellant gas diffuses radially inwards through the hot, dense, annular cloud of fissioning fuel and then flows axially out through a nozzle in the centre of one end wall (see Fig. 1). Extensive theoretical and experimental studies have been made to determine the feasibility of this technique[3,4]. One of the limiting factors in the performance of a gaseous vortex reactor[2] or its modified versions[1] is the deposit of fission fragments, beta rays and thermal radiation on the cavity wall. This is compounded by the fact that at low temperatures ($\leq$7,000 K) hydrogen is relatively transparent to radiation. This loss is not only detrimental to fuel economy and the criticality for nuclear chain reaction of the engine, but also enhances the heating of the cavity wall. It is to reduce this loss that the concept of a "dust curtain" in the cavity of a gaseous vortex reactor is introduced.

It is recognized that seeding of the propellant with refractory metallic particles is very effective in increasing both its opacity to the radiation flux and its collision cross-section for the fission fragments. Because of its high molecular weight, the seeding material is, however, a poor substitute for the propellant from the viewpoint of optimum engine performance, and for this reason it would be desirable to have the seeding particles suspended and retained in the cavity, much like the fission particles, without being constantly ejected with the propellant through the exhaust nozzle. It is found that seeding particles, appropriately granulated in mass and size, which are premixed and taken in with the propellant in vortex flow, can be made to have a peaked concentration in an annular region at a specific radial distance from the axis of the cylindrical cavity. This annular seeding particle cloud is called here the "dust curtain", and is located between the surface of maximum fuel concentration and the wall to shield the latter from the bombardment and radiation of the fission particles.

Before formulating the desirable concentration distribution of the dust in the flowing propellant, it is necessary to consider the kinetics of small suspended particles in a non-uniform gas. The presence of the second admixture (the fission particles) in the propellant gas can be ignored, because the maximum concentrations of these two admixtures in the gas are in separate locations. Following the kinetic theories of Waldmann[5] and Mason and Chapman[6], the suspended dust particles are treated as giant molecules. The collisions between propellant gas molecules (mass m_p, density n_p, mass density $\rho_p = m_p n_p$), and the spherical dust particles (radius r_d, mass m_d,

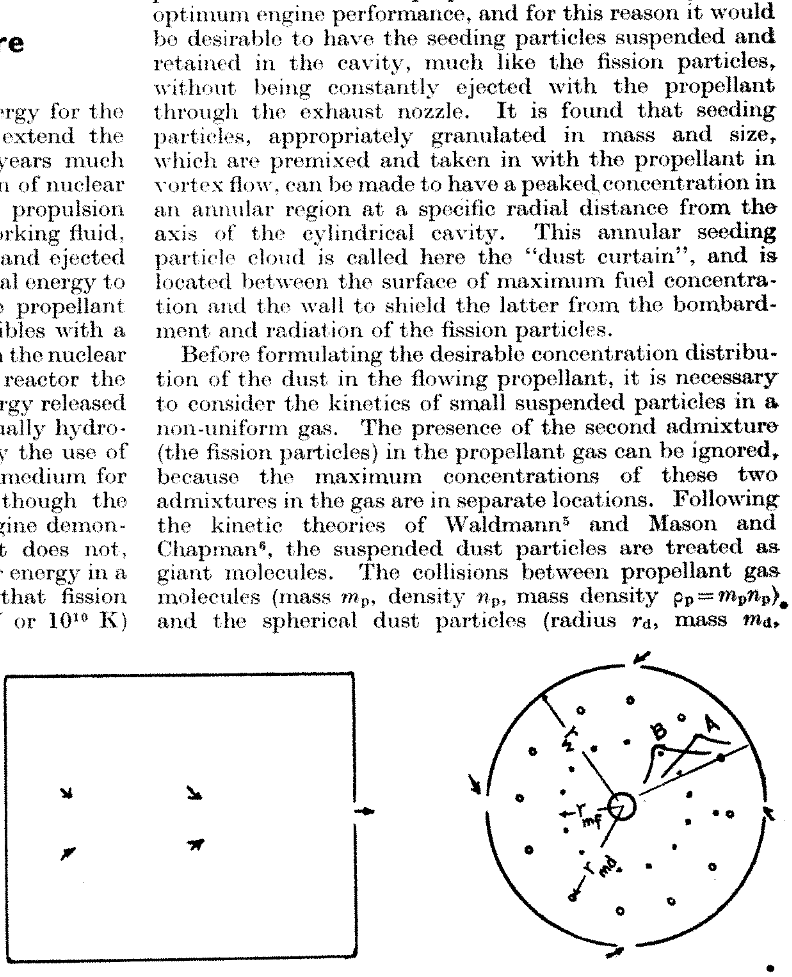

Fig. 1. Schematic gaseous vortex reactor. *A*, Distribution of ϱ_d/ϱ_p along r; B, distribution of ϱ_f/ϱ_p along r.

density n_d) are assumed to be elastic, a fraction α rebounding in random directions and the remainder specularly. The binary diffusion coefficient D_{dp} for such a quasi-Lorentzian gas can be expressed in the following manner[6]

$$\frac{1}{\rho_p D_{dp}} = \frac{8}{3}\left(\frac{2}{\pi m_p kT}\right)^{1/2}(\pi r_d^2)\left(1+\frac{4}{9}\alpha\right) \quad (1)$$

assuming $n_p \gg n_d$ and $m_d \gg m_p$.

Consider a binary mixture of inviscid gases, the propellant and the dust, in a steady, two-dimensional vortex flow of constant strength of vorticity $\Gamma = vr$, with a zero axial velocity in the annular region of interest and an inward radial velocity that is everywhere much smaller than the tangential velocity (see Fig. 1). In addition, the diffusion process is assumed to be non-turbulent, with negligible thermal diffusion and chemical reactions. The distribution of the density ratio of the gases ($w = \rho_d/\rho_p$) in the flow field can be formulated using the equations of continuity of the mixture flows and the diffusion velocity of the dust, following a similar mathematical deduction as in reference 2,

$$\frac{\dot M_p + \dot M_d}{\dot M_d} - \frac{1+w}{w} = \frac{2\pi \rho_d D_{dp}}{M_d}\left(\frac{d \ln w}{d \ln r} - \frac{m_d}{m_p}\frac{v^2}{RT}\right) \quad (2)$$

where R, T and $\dot M_p$ denote the gas constant (per unit mass), temperature and radial mass flow rate of the propellant gas respectively: $\dot M_d$, the radial mass flow rate of the dust. The value of $\dot M_d/\dot M_p$ is prescribed by the value of ρ_d/ρ_p at the inner boundary where the flow leaves the vortex; it gives the relative loss rate of seeding material and propellant. Equation (2) is completely analogous to the diffusion equation for the fission material in reference 2. If the dimensionless vortex flow v^2/RT is prescribed as a monotonically decreasing function of r, a simple maximum for $w(r)$ can be established with $w \to 0$ as $r \to \infty$. The position r_{md} of w_{max} may be determined by setting $dw/dr = 0$ in equation (2)

$$\frac{v^2}{RT} = \frac{\Gamma^2}{RTr_{md}^2} = - \frac{m_p}{m_d}\left(\frac{\dot M_p + \dot M_d}{2\pi \rho_p D_{pd}}\right)\left[1 - \left(\frac{1+w_m}{w_m}\right)\left(\frac{\dot M_d}{\dot M_p + \dot M_d}\right)\right] \quad (3)$$

An effective shielding of the wall (r_w) can be attained by setting $r_{mf} < r_{md} < r_w$ where r_{mf} denotes the location of the maximum concentration of the fuel. A desirable value of r_{md} can be obtained by a judicious choice of size and mass of dust particles relative to those of the fission particles and also those of the propellant gas (see equation (3)).

This work was initiated while I was a consultant to the Vehicle Propulsion Division of NASA Office of Space Science and Applications. I thank Dr R. B. Morrison for his interest and encouragement, and Mr Keith Bekofske who helped in the calculations to check the feasibility of the idea.

Effects of Shear Treatment on Drag-reducing Polymer Solutions and Fibre Suspensions

NUMEROUS workers have put forward models which attempt to explain the complex behaviour of drag reducing polymer solutions, but no explanation has been universally accepted. The ability of apparently identical batches of a polymer to give widely varying results has now been ascribed to variations in mixing procedures, though apparently no systematic investigation of the reason for such behaviour has been made. In the experiments reported here, concerning drag reduction in 'Polyox *WSR* 301' solutions and asbestos fibre dispersions, attention is focused on the differences in behaviour in large and small bore pipes and the changes in this behaviour brought about by shear thinning treatment.

Tubes of 0·115 cm bore (70 cm length) and 1·43 cm bore (300 cm length) were used, at a Reynolds number of approximately 2×10^4 in each case. 'Polyox' solutions were prepared by adding water quickly and in bulk to a dispersion of 'Polyox' powder in glycol. The asbestos fibres, kept in a surfactant dispersion, were specially prepared by Turner Bros Asbestos Co. Ltd to maintain a high length to diameter ratio. Surfactant solution was used in diluting the asbestos, and the asbestos drag measurements were referred to the drag of the surfactant solution, though in all cases the surfactant gave drag figures identical with water.

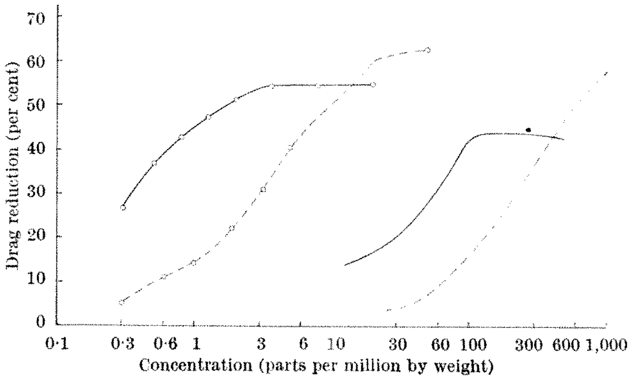

Fig. 1. Drag reduction versus concentration, 'Polyox *WSR* 301' and asbestos fibre suspensions. 'Polyox *WSR* 301': ○—○, 1·43 cm tube; ○ - - - ○, 0·115 cm tube. Asbestos: ———, 1·43 cm tube; - - -, 0·115 cm tube.

Fig. 1 shows drag reduction as a function of concentration in both tubes, for 'Polyox' and asbestos. This is believed to be the first time that high values of drag reduction (44 per cent) have been obtained with dilute fibre dispersions (100 parts per million by weight).

Table 1. DRAG REDUCTION WITH 'POLYOX *WSR* 301': EFFECTS OF SLIGHT SHEAR THINNING

'Polyox' concentration (parts per million by weight) (w.p.p.m.)	Drag reduction 1·43 cm diameter tube (per cent)	
	First pass	Second pass
0·64	40	26
0·32	27	13

Table 1 shows the degradation in performance obtained when 'Polyox' solutions were passed through the 1·43 cm tube, collected and passed through again. A similar experiment was carried out on asbestos dispersions, but no change was observed in this case. It appears that even the slight shear thinning applied during the first pass has markedly reduced the polymer effectiveness in this situation.

To carry the investigation further, quantities of the original 0·1 per cent 'Polyox' solution and 0·1 per cent asbestos dispersion were subjected to shear treatment for one hour by recirculation through an impeller pump, and

Table 2. DRAG REDUCTION WITH 'POLYOX *WSR* 301' AND ASBESTOS; EFFECTS OF PROLONGED SHEAR THINNING

Pipe diameter	Condition	'Polyox *WSR* 301' (10 w.p.p.m.) per cent	Asbestos fibres (50 w.p.p.m.) per cent
0·115 cm	Unpumped	51	49
	Pumped	50	42
1·43 cm	Unpumped	54	44
	Pumped	1	33

were then tested in both tubes. The results, compared in Table 2 with results obtained for unpumped samples, demonstrate a remarkable change in behaviour of 'Polyox'; whereas the drag reduction figure in the small pipe changed negligibly with pumping, in the large pipe it has dropped from 54 per cent to zero, within experimental error. The effectiveness of asbestos, on the other hand, has only dropped slightly in both tubes. The pumped 'Polyox' was also tested as a function of concentration in the small tube, but the resultant graph was so close to the result shown in Fig. 1 as to be indistinguishable.

These results demonstrate that drag reduction with polymers in turbulent pipe flow is dependent on the shear history of the fluid only when the pipe is comparatively large. It is my opinion, however, that it is the scale of turbulence, and not simply pipe size, which is the parameter governing this effect.

Of the numerous physical models which have been put forward in an attempt to explain all the properties of drag reducing polymers, that proposed by Alan White[1] has hitherto appeared the most reasonable. White supposes a dual action by the polymer; a thickening of the laminar sublayer, which occurs whether the polymer is "fresh" or "shear treated", and a turbulence damping effect, which occurs only when the polymer is not shear treated or aged.

The present results suggest that for a full description of drag reduction, one needs to specify some parameter which is linked to the pre-treatment of the polymer; the "stringiness" at high concentration, in other words the tendency to form thread-like filaments, is an obvious candidate. The results may be explained by assuming that the stringiness of, say, a 0·1 per cent 'Polyox' solution is linked to the size of energy absorption domains (presumably consisting of matrices or agglomerates of molecules containing large entrapped volumes of water) which interact in some way with flow instabilities to inhibit their growth.

If the permanent thinning of polymer solutions by the application of shear were simply a reduction in domain dimensions, one would expect no decrease in effectiveness in situations where the reduced domain size (down to molecular dimensions) was still adequate to interact with the largest energy dissipating vortices encountered (small tube, high wall shear stress), but a greatly reduced drag reducing effect in situations where the scale of turbulence was much larger (large tube, low wall shear stress). The results described in this report exhibit precisely this behaviour, and it is suggested as a consequence that polymer drag reduction should again be regarded as a "single-action" phenomenon; that of instability damping, where the physical scale of turbulence and a stringiness type parameter are important factors.

The results obtained for asbestos, while being interesting in themselves, tend to reinforce this model. Presumably the individual asbestos fibres are large enough to affect the largest turbulence scale in the large tube, and the smaller observed change in drag reduction on pumping is probably due to a degree of flocculation or scission brought about by pumping. Asbestos fibres may be found to lose their drag reducing properties in turn if the turbulence scale is pushed high enough.

It seems probable that organic polymers have little future in recirculatory pumping systems, for they lose their invaluable large domain size/turbulence damping properties at low values of shear stress. Ionic soaps akin to cetramide may repay study, but fibres will certainly repay further investigation, for they seem to be on the right scale of dimensions for drag reduction in large scale turbulence. They are also more tractable than polymers, being much larger, and could make the basic understanding of drag reduction an easier problem to study.

Energy Resonances between Molecular Species in CO_2 Gas Lasers

IMPORTANT requirements for the attainment of population inversion needed in the operation of molecular gas laser systems are that population of the upper laser level and depopulation of the lower level(s) should be attained as far as possible through super-elastic collisions with impurity species[1]. These and other conditions[1,2] are well satisfied by CO_2 lasers operating in a number of gas mixtures[3] such as CO_2, CO_2-N_2, CO_2-N_2-H_2O, CO_2-N_2-H_2O-He. For example, it is well known[4] that for lasers operating in CO_2-N_2 mixtures, the close energy resonance between the metastable $N_2(X^1\Sigma_g^+)$ and the upper laser level $CO_2(X^1\Sigma_g^+, 0, 0^\circ, 1)$ provides a very efficient super-elastic collision channel for selective population of this CO_2 level. It is also possible that other low-lying vibrational levels of $N_2(X^1\Sigma^+)$ may play similar parts.

It is the purpose of this report to draw attention to a number of other close energy resonances which exist between laser levels of CO_2, and the diatomic and triatomic species expected to be present in various discharges in which CO_2 laser action has been achieved. CO_2 laser action in the 9·6 micron and 10·6 micron bands is achieved in a variety of discharges through pure CO_2 (and additives) at a few millimetres pressure. Efficiency is increased by addition of N_2, H_2O and He[3]. Efficient CO_2 laser action has recently been reported at atmospheric pressure, excited by transverse high voltage discharges[5].

Varying amounts of the following species will be expected to be present in the laser discharges depending on excitation conditions

$CO_2, CO_2^+, CO, CO^+, O_2, O_2^+, C_2, C_2^+$

$N_2, N_2^+, NO, NO^+, CN, CN^+$

$H_2O, H_2O^+, OH, OH^+, CH, CH^+, NH, NH^+$

There is optical and mass spectrographic evidence for most of these. For example, the CO_2^+ bands are the major contributor to the optical spectrum of discharged CO_2. Before a quantitative examination can be made of the excitation kinetics of CO_2 laser levels, energy resonances between them and levels of the above species must be examined because high excitation cross-sections will be expected in super-elastic collisions which involve close energy resonances. The energy range (0–2,349 cm^{-1}) of interest implies that only low-lying ($v = 1$) vibrational levels of the electronic ground state of species need be considered here. Further, most CO_2 lasers operate at gas temperatures of about 400 K[3], which implies rotational development of 300 cm^{-1} of each vibrational level. Thus in the review of energy resonances made here, each vibrational level is treated as an energy band of about 300 cm^{-1} width. The relative locations of the energy levels of the species listed above are compared in Fig. 1 with the location of the CO_2 laser levels. For ease of comparison, resonant levels are separated from non-resonant levels in this figure. Data for diatomic species were taken from Wallace's compilation[6], while data for polyatomic species were taken from Herzberg's compilation[7]. No data were available for C_2^+ or H_2O^+. The ground state of C_2 was called a $^1\Sigma$ by Wallace[6].

It is clear from Fig. 1 that, in addition to the strong resonance between the upper laser level $CO_2(0,0^\circ,1)$ and $N_2(X^1\Sigma_g^+, v=1)$ to which reference has already been made, a number of other strong and partial resonances exist. In particular, the stable ion NO^+, which plays important parts in ionospheric physics, exhibits a somewhat stronger energy resonance than N_2 with the upper laser level $CO_2(0,0^\circ,1)$. CO, CO^+ and N_2^+ also exhibit strong energy resonances with the upper laser level. They can all thus play parts in maintaining the population inversion. Vibrational levels of N_2^+, like those of N_2, are metastable because both molecules are homonuclear. It is also noted that the (2,0,0) level of CO_2^+ is in partial resonance with $CO_2(0,0^\circ,1)$. It is also seen in Fig. 1 that the two lower CO_2 laser levels, $(0,2^\circ,0)$ and $(1,0^\circ,0)$, are in resonance with CO_2^+ (1,0,0 and 0,0,1), with H_2O $(0,1^\circ,0)$ and with O_2. Because of its metastability and its relatively long life, $O_2(v=1)$ probably contributes to the collisional population of the lower laser levels, although O_2 is easily dissociated by energetic electron collision through the operation of the Franck-Condon principle. It may thus not be present in large quantities.

Witteman[9] has shown that H_2O resonances increase the depopulation of the lower laser level. Excited CO_2 transfers its energy to unexcited H_2O in super-elastic collisions. The resulting excited H_2O is strongly collisionally de-excited by other H_2O molecules. It is thus not unlikely that the ground state CO_2^+ molecules can similarly act to depopulate the lower laser levels of CO_2. The (2,0,0) CO_2^+ level may similarly act to depopulate the upper laser level of CO_2. The energy resonance between rotational structures in this case is not so large, however, and decreases with decrease in temperature. The energy resonance between the lower CO_2 and CO_2^+ levels is contrastingly larger, and thus retained even at lower (200 K) temperatures. Thus the balance between CO_2^+ depopulation of upper and lower levels moves towards increasing population inversion with decreasing temperature. This effect is observed experimentally[3]. Species arising from CO_2 alone must in all probability be responsible for some population inversions in pure CO_2 lasers. The possible effects of ionic species like CO_2^+ and NO^+ cannot be overlooked in the operation of lasers operating in many discharges, including those maintained by high voltage excitation at atmospheric pressure. Relatively little work has been done on the kinetics of excitation of laser levels[9,10] and the resonances described in this report do not seem so far to have been considered.

This work has been supported by research grants from the Defence Research Board of Canada and from the National Research Council of Canada.

Haemoglobin α Chain Duplication in Barbary Sheep, *Ammotragus lervia*, *Pallas, 1777*

EVIDENCE for the existence of two non-allelic Hb_α structural loci in the domestic goat has been presented[1,2]. The products of these loci, termed $^I\alpha$ and $^{II}\alpha$ chains[3], differ in at least four positions. Glycine, alanine, leucine and asparagine occupy positions 19, 26, 113 and 115 in the $^I\alpha$ chain, respectively, whereas serine, threonine, histidine and serine are present in these positions of the $^{II}\alpha$ chain[2]. The percentages of $^I\alpha$ and $^{II}\alpha$ chains in red cell haemolysates

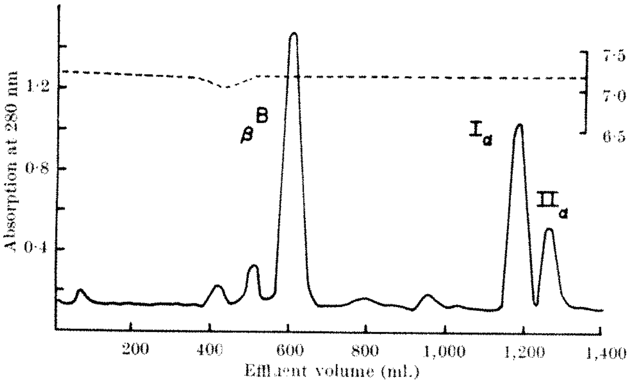

Fig. 1. Separation of the α and β chains of haemoglobin from Barbary sheep No. 503 by CM-cellulose chromatography. Globin (280 mg) was used as starting material.

of normal AA goats are about 72 and 28, indicating that evolution of the duplicated Hb_{α} loci is associated with a three-fold decrease (or increase) in Hb_{α} locus efficiency[3]. No such α chain multiplicity was observed in the domestic sheep[4].

We describe here similar observations for the α chains of the haemoglobin from Barbary sheep (*Ammotragus lervia, Pallas, 1777*). A distinct haemoglobin heterogeneity was found in this animal species[5-7]; the β chain of one of these haemoglobins was recently characterized[7].

Material was available from two animals; one (numbered 8) which was homozygous for haemoglobin type C was studied previously[7], while a second (numbered 503) with a homozygosity for Hb-B was obtained commercially. The α and β^{C} chains from globin of animal numbered 8 were separated by countercurrent distribution[7], while the globin from animal numbered 503 was analysed by CM-cellulose chromatography[3]. Fig. 1 illustrates the separation of the haemoglobin chains by chromatography; one major β chain (the β^{B} chain) was eluted first, followed by two α chains, which were completely separated from each other. The relative amounts of the $^{\rm II}\alpha$ zone were 25·7, 24·0 and 24·8 per cent in triplicate analyses, indicating that the $^{\rm I}\alpha$ and $^{\rm II}\alpha$ chains in this animal are present in a ratio of about 3 to 1, similarly as observed in the normal AA goat[3].

The $^{\rm I}\alpha$ and $^{\rm II}\alpha$ chains were isolated from the respective zones of the three chromatograms by passage through 60 × 2·5 cm columns of 'Sephadex *G*-25' in 0·5 per cent formic acid, and subsequent freeze drying of the protein containing zones. Structural analyses were limited to the determination of the amino-acid compositions of the tryptic peptides, and of the chymotryptic peptides from the insoluble cores. The techniques are the same as those used in the study of goat and sheep α chains[2,4].

No differences were observed between the amino-acid compositions of the tryptic peptides T-1; T-2; T-3; T-5; T-6; T-7,8; T-9^{a}; T-10; T-11; T-10,11 and T-14 of the $^{\rm I}\alpha$ chain and those of the same peptides of the $^{\rm II}\alpha$ chain. Nor do the amino-acid compositions of these peptides differ from the compositions of the corresponding peptides of goat α chains[2]. The chymotryptic peptides, originating from positions 99 through 106 and from positions 118 through 141 of the cores from both α chains, also had identical amino-acid compositions, which again did not differ from those of the corresponding goat α chain core peptides.

The compositions of the tryptic peptides T-4 and T-9^{b} and of a chymotryptic core peptide from both chains are presented in Table 1. Comparison of these data with those observed for the corresponding peptides of the goat $^{\rm I}\alpha$ and $^{\rm II}\alpha$ chains[2] indicates: (*a*) the amino-acid compositions of the peptides T-4 and core C-2 of the $^{\rm I}\alpha$ chain are identical to those of the goat $^{\rm I}\alpha$ chain; (*b*) the amino-acid compositions of peptides T-4 and core C-1 of the $^{\rm II}\alpha$ chain also do not differ from the corresponding peptides of the goat $^{\rm II}\alpha$ chain, except for the presence of one more residue of threonine and one less residue of alanine in the T-4 peptide of the goat $^{\rm II}\alpha$ chain; (*c*) the T-9^{b} peptides from both chains have identical amino-acid compositions, but differ from the T-9^{b} peptide of the goat α chains by the presence of one less residue of aspartic acid, which is replaced by glutamic acid. Similar analyses made on the mixture of the two α chains from Barbary sheep numbered 8 gave comparable results. When the amino-acid residues of the two T-4 peptides and of the core peptides are placed in sequence by analogy with known sequences of goat and sheep α chains[2,4], three differences between the two α chains of Barbary sheep haemoglobin are apparent. Positions 19, 113 and 115 of the $^{\rm I}\alpha$ chain are occupied by glycine, leucine and asparagine, respectively, whereas serine, histidine and serine are present in these positions of the $^{\rm II}\alpha$ chain. An alanyl residue likely occupies position 26 of both chains (alanine in goat $^{\rm I}\alpha$ chain and threonine in goat $^{\rm II}\alpha$ chain).

* Data are presented as numbers of residues relative to lysine, arginine or histidine. The nomenclature used is the same as for the peptides from goat α chains[2]. Numbers between parentheses denote amino-acid compositions of corresponding goat α chain peptides.

These findings, although observed in only two animals, indicate a chemical heterogeneity of haemoglobin from Barbary sheep, which is closely comparable with that of the haemoglobin from the domestic goat. It therefore seems reasonable to assume that this heterogeneity results from a similar genetic factor, namely duplication of the Hb_{α} locus and subsequent evolution of the resulting $^{\rm I}\alpha$ and/or $^{\rm II}\alpha$ loci. Our observations add another animal species to the growing list of mammals in which multiplicity of Hb_{α} loci has been demonstrated (summarized in ref. 3). The similarity of the differences between the $^{\rm I}\alpha$ and $^{\rm II}\alpha$ chains from Barbary sheep and of those between the $^{\rm I}\alpha$ and $^{\rm II}\alpha$ chains from the goat supports the hypothesis that species *Ammotragus lervia, Pallas, 1777*, should be placed in the genus *Capra* rather than in the genus *Ovis*, as is most frequently the case[8].

In vivo Testing of the Fletcher–Huehns Hypothesis of Functional Differences of Iron Atoms bound by Transferrin

RECENTLY Fletcher and Huehns[1-3] proposed an interesting hypothesis on the possible functional difference between the two iron binding sites of the iron transport protein, transferrin. They presented evidence from *in vitro* studies that iron uptake by the two binding sites is random, while the release of iron to erythroid precursors occurs preferentially from one site, which they arbitrarily designated the A site. This site is also postulated to be important in the transfer of iron to the placenta of pregnant animals. The other site, designated B, is somehow concerned with delivery of iron to storage depots. Complete saturation of both sites with iron produces greater transfer to erythroid precursors and/or storage depots. The concept of selective release of iron from functionally different binding sites on the transferrin molecule is potentially of great importance and warranted repetition of Fletcher and Huehns's *in vitro* experiments and the exploration of their hypothesis *in vivo*.

The procedures for collecting blood enriched with reticulocytes and incubating them with labelled transferrin were those described originally by Jandl and co-workers[4,5] and modified by Kornfeld[6]. Purified, iron-free, human transferrin (Behringwerke) was used in all experiments.

Transferrin, 100 per cent saturated with ^{59}Fe, was preincubated with rabbit reticulocytes until 30 to 50 per cent of the ^{59}Fe was removed from solution. The transferrin solution was freed of reticulocytes by centrifugation and then incubated with fresh reticulocytes for 60 min at 37° C. The uptake of iron from the predominantly B site binding of this transferrin solution was diminished by 70 per cent compared with the uptake from a control preparation of ^{59}Fe-transferrin of equal saturation that had ^{59}Fe bound randomly to A and B sites. Furthermore, when ^{59}Fe was added back to the preincubated transferrin to restore 100 per cent saturation, ^{59}Fe uptake by fresh reticulocytes was restored to the control levels, confirming the original observations of Fletcher and Huehns.

To test *in vivo* the hypothesis of selective iron distribution from the different binding sites of transferrin, double-labelled transferrin was prepared. Transferrin was totally saturated with ^{59}Fe and then incubated with rabbit reticulocytes until 30 to 50 per cent of the ^{59}Fe had been removed from the transferrin solution (presumably most of the ^{59}Fe was removed from site A). Complete saturation was restored by adding ^{55}Fe to achieve selective labelling of site A while site B retained its original ^{59}Fe. Alternatively, the transferrin was first saturated with ^{55}Fe and the ^{59}Fe was added to replace the iron removed by incubation with reticulocytes. The transferrin solutions with selective tagging of A and B sites were injected intravenously into rats. The 2 h uptake of radioactivity, expressed as a percentage of the dose administered, was calculated for selected organs which were analysed for ^{55}Fe and ^{59}Fe simultaneously by the method of Katz and co-workers[7]. In seven experiments, pregnant rats were studied for evidence of selective placental radio iron transfer (Table 1).

A significant difference in the tissue distribution of radioactive iron was observed in only two instances in these rats injected *in vivo*. Selective labelling of site B produced enhanced uptake by the foetuses of pregnant rats which is contrary to the prediction of the Fletcher–Huehns hypothesis. Diminished radio iron in the blood of rats injected with site A labelled transferrin in comparison with uniformly labelled transferrin but not with site B labelled transferrin seems to have statistical rather than biological significance. Most noteworthy is the lack of selective uptake of radio iron of a specific type by bone marrow, liver or spleen, receptor tissues with expected polarity for selectively labelled transferrin.

We conclude from these studies, which were designed to test *in vivo* the release of iron from selectively labelled transferrin, that the differences of iron transfer predicted by *in vitro* studies are not demonstrated and that a re-examination of Fletcher and Huehns's attractive hypothesis is necessary.

Table 1. PERCENTAGE UPTAKE OF RADIO IRON (MEAN ± SD)

Tissue	Equal labelling of transferrin sites A and B (9)	Predominant labelling of transferrin site B (20)	Predominant labelling of transferrin site A (13)	Significance Student's *t* test
Bone marrow	44·1 ± 10·1	44·6 ± 18·1	47·8 ± 9·7	N.S.
Blood	16·2* ± 1·1	15·4 ± 12·4	11·4* ± 5·1	0·05 > *t* > 0·025
Liver	18·2 ± 6·3	16·9 ± 12·0	14·2 ± 7·1	N.S.
Spleen	2·2 ± 0·6	3·4 ± 2·6	3·3 ± 2·7	N.S.
Maternal placenta		(4) 0·2 ± 0·16	(3) 0·2 ± 0·13	N.S.
Foetal placenta		1·9 ± 0·81	1·9 ± 0·46	N.S.
Foetus		2·7* ± 2·09	0·91* ± 0·48	0·05 > *t* > 0·025

Rats (250–380 g) were injected intravenously with transferrin totally labelled with radio iron on selected iron-binding sites. Tissue distribution of ^{59}Fe and ^{55}Fe expressed as per cent of injected radioactivity was measured at 2 h. The number of experiments is given in parentheses and significant differences are shown by *. Bone marrow mass is calculated as 2 per cent of body weight, blood volume as 5 per cent of body weight. Four to ten foetuses in the last third of gestation were analysed for each pregnant rat.

This study was supported in part by an AEC contract and a US Public Health Service grant. M. C. is a research scholar under the Fulbright–Hays programme; E. B. B. is the recipient of a US Public Health Service research career development award.

Crystalline Fc prepared in High Yield from Normal Human IgG

CRYSTALLINE rabbit Fc fragment is simple to prepare in high yield from the corresponding IgG by cysteine-activated papain digestion[1]. Although crystalline products can be obtained from human myeloma globulins, only one report[2] has hitherto appeared describing an analogous substance from normal human IgG. The conditions for digestion of normal rabbit or human IgG were markedly different. One-tenth the ratio of enzyme: antibody was used, and the reaction time was reduced from 16 h to 30 min for the human material. In our hands, although a solid human Fc was obtained by the method of Hershgold *et al.*, the material did not crystallize, and the yield was low. We therefore decided to re-examine the cysteine-activated digestion conditions. The results are reported here, together with the finding that the crystalline Fc, obtained in high yield, may be principally of a single Gm allotype, reflecting the allotypy of the IgG 1.

Human IgG was prepared from the serum of single Caucasian individuals by DEAE-cellulose chromatography[3], and checked for purity by immunoelectrophoresis. In preliminary experiments, an IgG which contained an anti-D rhesus agglutinin was used to indicate approximately the conditions necessary for cleavage. Globulin was incubated with 1 per cent of its weight of crystalline papain (Worthington) in 10 mM cysteine and 2 mM EDTA at 37° and *p*H 7. Although agglutination was abolished within 1·5 h, the globulin immunophoretic arc had not competely disappeared. These conditions were, nevertheless, selected for studies on a larger scale.

Incubation was followed by dialysis against 10 mM sodium phosphate (*p*H 7·6) at 4° for 6 h, and chromatography of the digestion mixture on carboxymethyl-cellulose as described by Franklin[4]. This resulted in two well separated peaks, the first containing Fc and the second containing F(ab). Both peaks contained undigested IgG. The F(ab) (molecular weight about 50,000: from calibrated 'Sephadex *G*-200' columns[5]), when derived from an anti-D agglutinin, was the only digestion fragment to exhibit blocking of the original IgG by previous incubation with target cells.

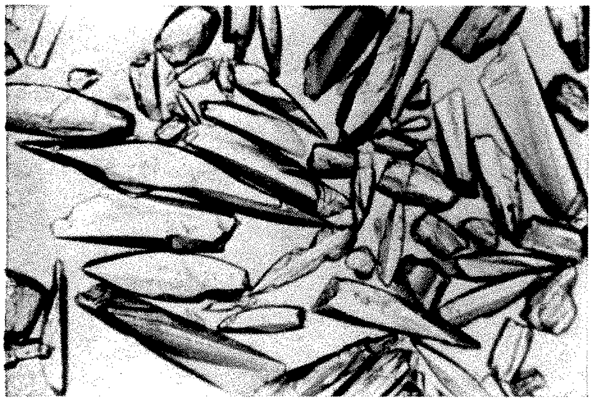

Fig. 1. Crystalline Fc from normal human IgG by papain digestion. × 20.

Upon concentration of peak 1 to a small volume by membrane filtration, a large yield of crystals was obtained (Fig. 1). Chromatography on 'Sephadex *G*-200' of the mother liquors after removal of crystals by centrifugation is illustrated in Fig. 2*a*, from which it can be seen that IgG is also present, confirmed by double diffusion on agar and immunophoresis. The relative amounts of Fc and IgG are not deducible from this figure, because much of the Fc has been removed by centrifugation. Recrystallization was easily effected from 200 mM phosphate *p*H 7·6, by dialysis at 4° against 2 mM phosphate buffer. Chromatography of the product after three recrystallizations is illustrated in Fig. 2*b*. The molecular weight of the crystalline product is about 50,000, and it gives a single line on immunoelectrophoresis. The yield of crystals is frequently over 60 per cent of the theoretical, based on the IgG actually destroyed. Preliminary allotyping data are given in Table 1.

Table 1. ALLOTYPING OF IgG AND CRYSTALLINE Fc FRAGMENT

Sample	Allotype Gm (1)	Gm (5)	Gm (21)
D IgG	−	+	−
D Fc	−	(±)*	−
L IgG	+	+	+
L Fc	+	−	−

* Fc present at 8 mg/ml.; Gm(5) present < 0·25 mg/ml.

Of the four classes of human IgG, IgG 3 is the most sensitive to papain, followed by IgG 1, and then IgG 2 and IgG 4 which have much lower sensitivities. It is clear that of the total crystalline product, less than 3 per cent is derived from IgG 3 (the Gm 5 and Gm 21 markers), and therefore molecules bearing Gm 1 or non-Gm 1 account for most of the crystalline protein in the examples described. IgG 2 and IgG 4 contribute only 14 per cent[6] of the total IgG in serum, and cannot therefore explain the yield. Until more data are obtained from other allotypes, and the undigested IgG is examined, it cannot be established whether co-crystallization or mixed crystals have resulted in contamination of the Fc allotype(s) obtained from IgG 1. Such contamination must, however, be small. This ignores the possibility that the L IgG individual examined could well be heterozygous for Gm 1, and the crystals could be 50 per cent non-Gm 1.

From the results of recent work[7,8], it seems that the Gm 1 and non-Gm 1 specificities of IgG 1 subclass are sensitive to prolonged papain digestion. Pepsin-produced pFc′ fragments retain the Gm allotypy of their respective Fc molecules, but on incubation with papain, or by exhaustive incubation of IgG with papain, such markers are lost. Our incubation conditions fortuitously represent circumstances in which papain-sensitive bonds in IgG 1 molecules which connect Fc to Fd are ruptured quantitatively, and yet further breakdown to Fc′ is slight. Fc derived from IgG 3 is either removed during recrystallization or principally converted to Fc′ during 1·5 h incubation with papain. This arc may have been overlooked in our immunoelectrophoresis patterns.

It will be useful to have normal human IgG more easily available than paraproteins for X-ray crystallography. Moreover, studies on crystalline fragments of a single IgG 1 allotype among families may be very informative about the molecular nature of their isotypic specificity.

We thank the Medical Research Council and the East Grinstead Research Trust for financial support, Mr C.

Darke for the anti-D agglutinin, and Drs C. Ropartz and L. Rivat for allotyping data.

Use of Phenylalanyl-tRNA–Guanosine-5′-Triphosphate–TI$_u$ Complex in Peptide Bond Formation

IT has been demonstrated[1-10] that in bacterial systems a complex, designated complex II, that is composed of aminoacyl-tRNA, GTP, and the heat labile transfer factor TI$_u$* serves as an intermediate in the binding of aminoacyl-tRNA to ribosomes and in the elongation of polypeptide chains. When Phe-tRNA from complex II is bound to a ribosome-poly U complex carrying AcPhe-tRNA at the donor site, most of the Phe-tRNA bound to the ribosomes interacts with the AcPhe-tRNA giving rise to AcPhe-Phe-tRNA at the acceptor site[6,10,12,13]. Phe-tRNA from complex II is also bound at the acceptor site of a ribosome–poly U complex having an unoccupied donor site, but in this case very little dipeptide is formed[9,10]. In both instances, approximately one GTP from complex II is cleaved for each Phe-tRNA bound to the ribosomes[9,10,14,15]. Lack of dipeptide formation is also observed in the presence of the antibiotic, sparsomycin[6,13,16], or when the GTP analogue 5′-guanylmethylene diphosphonate is substituted for GTP[12,13]. Our results indicate that almost none of the Phe-tRNA from complex II bound to the acceptor sites before the addition of AcPhe-tRNA to donor sites is incorporated in peptide chain.

AcPhe-tRNA bound to ribosomes at 5 mM Mg^{2+} in the presence of GTP and initiation factors reacts almost quantitatively with puromycin (Table 1), indicating that it is bound at the donor sites of the ribosomes. The binding of Phe-tRNA from complex II to these ribosomes results in a decrease in the amount of AcPhe-tRNA that reacts with puromycin, indicating the formation of AcPhe-Phe-tRNA at the acceptor sites. Identification of the products bound to the ribosomes supports this conclusion and demonstrates that 60 per cent of the AcPhe-tRNA and 70 per cent of the Phe-tRNA from complex II are present as AcPhe-Phe-tRNA. The remainder of the products are AcPhe-tRNA and Phe-tRNA; there is no detectable tripeptide.

Table 1. IDENTIFICATION OF PRODUCTS FORMED AS A RESULT OF THE BINDING OF ^{3}H-Phe-tRNA FROM COMPLEX II TO RIBOSOMES CARRYING Ac-^{14}C-Phe-tRNA

Additions to ribosomes carrying Ac-^{14}C-Phe-tRNA	Bound to ribosomes		Released by puromycin		Recovered after alkaline hydrolysis	
	Ac-^{14}C-Phe	^{3}H-Phe	Ac-^{14}C-Phe	^{3}H-Phe	Ac-^{14}C-Phe	Ac-^{14}C-Phe-^{3}H-Phe
(*A*) None	10·7	—	10·2	—	10·8	—
(*B*) ^{3}H-Phe-tRNA in complex II	10·4	8·4	3·0	1·0	3·2	6·0

Results are in pmoles/0·1 mg ribosomes.

Deoxycholate washed ribosomes, transfer factors TI$_s$, TI$_u$, and TII, ^{3}H- and ^{14}C-Phe-tRNA were prepared as previously described[9,17] and stored at −90° C. Initiation factors f$_1$ and f$_2$[18], complex II[9] containing ^{3}H-Phe-tRNA and γ-^{32}P-GTP and Ac-^{14}C-Phe-tRNA[19] were prepared as previously described. (*A*) To prepare ribosomes carrying Ac-^{14}C-Phe-tRNA, 5 mg ribosomes and 0·5 mg poly U were incubated for 5 min at 37° in 1 ml. of buffer 5 (Tris-HCl, *p*H 7·7, 0·05 M; dithiothreitol, 5 mM; NH$_4$Cl, 80 mM; KCl, 80 mM; and MgCl$_2$, 5 mM). The mixture was cooled and f$_1$ (150 μg of protein), f$_2$ (225 μg of protein), GTP (0·5 μmole) and Ac-^{14}C-Phe-tRNA (1·5 nmoles) were added in a final volume of 5 ml. of buffer 5. The mixture was incubated for 15 min at 25°, cooled, and layered over 5 ml. of buffer 5 containing 10 per cent sucrose. The ribosomes were collected by centrifugation at 150,000*g* for 90 min, and the ribosomal pellet was suspended in 2 ml. of buffer 5 and stored at −90° C. (*B*) To 5 mg of ribosomes carrying Ac-^{14}C Phe-tRNA, prepared as described above, was added complex II, containing 1·5 nmoles of ^{3}H-Phe-tRNA and 2·5 nmoles of γ-^{32}P-GTP, and the mixture was incubated for 10 min at 0° C. The ribosomes were collected by centrifugation through buffer 5 containing 10 per cent sucrose and resuspended as described above. The amounts of Ac-^{14}C-Phe-tRNA and ^{3}H-Phe-tRNA bound to ribosomes were measured by the 'Millipore' filter method as previously described[17]. To determine the release by puromycin, 0·2 mg of the ribosomal complexes and 1·0 mM puromycin were incubated for 30 min at 0° C in 0·25 ml. buffer 5, and the amount of ethyl acetate extractable material was determined as described by Leder and Bursztyn[20]. The products bound to 0·8 mg of ribosomal preparations *A* and *B* were liberated by alkaline hydrolysis[10] and identified by chromatography on 'Sephadex *G*-15' equilibrated in 0·5 M acetic acid, a modification of the procedure described by Bretthauer and Golichowski[21].

Table 2. IDENTIFICATION OF PRODUCTS FORMED AS A RESULT OF THE BINDING OF Ac-^{14}C-Phe-tRNA TO RIBOSOMES CARRYING ^{3}H-Phe-tRNA FROM COMPLEX II

Additions to ribosomes carrying ^{3}H-Phe-tRNA	Bound to ribosomes		Released by puromycin		Recovered after alkaline hydrolysis	
	Ac-^{14}C-Phe	^{3}H-Phe	Ac-^{14}C-Phe	^{3}H-Phe	Ac-^{14}C-Phe	Ac-^{14}C-Phe-^{3}H-Phe
(*A*) None	—	6·5	—	0·5	—	—
(*B*) Ac-^{14}C-Phe-tRNA	9·9	5·7	8·8	0·7	9·2	0·3

Results are in pmoles/0·1 mg ribosomes.

(*A*) To prepare ribosomes carrying ^{3}H-Phe-tRNA from complex II, 5 mg of ribosomes and 0·5 mg of poly U were incubated for 5 min at 37° C in 1 ml. of buffer 5. The mixture was cooled and complex II, containing 2 nmoles of ^{3}H-Phe-tRNA and 3·3 nmoles of γ-^{32}P-GTP, was added in a final volume of 5 ml. of buffer 5. The mixture was incubated for 10 min at 0° C and layered over 5 ml. of buffer 5 containing 10 per cent sucrose. The ribosomes were collected and resuspended as described in Table 1. (*B*) To 5 mg of ribosomes carrying ^{3}H-Phe-tRNA from complex II were added f$_1$ (150 μg protein); f$_2$ (225 μg protein); GTP, 0·5 μmole; and Ac-^{14}C-Phe-tRNA, 1·5 nmoles. The ribosomes were collected and determinations were conducted as described in Table 1.

At 5 mM Mg^{2+} Phe-tRNA from complex II is bound to ribosomes with unoccupied donor sites (Table 2), and very little of the bound Phe-tRNA reacts with puromycin. This and other data[9] indicate that the Phe-tRNA is bound at the acceptor sites. The amount of Phe-tRNA bound to ribosomes having empty donor sites rarely exceeds 5–7 pmoles per 0·1 mg ribosomes, whereas 8–10 pmoles are bound to ribosomes carrying AcPhe-tRNA (Table 1). In the conditions described in Tables 1 and 2, approximately one GTP is hydrolysed per Phe-tRNA bound to the ribosome[9,10]. The amount of AcPhe-tRNA bound to the ribosomes in the presence of initiation factors and GTP is approximately 8–10 pmoles whether or not the ribosomes carry Phe-tRNA from complex II. In addition, about the same amount of AcPhe-tRNA is released by puromycin whether or not Phe-tRNA has been previously bound at acceptor sites. When AcPhe-tRNA is bound to ribosomes carrying Phe-tRNA from complex II, less than 10 per cent of the AcPhe-tRNA and the Phe-tRNA interact to form dipeptide (Table 2). Incubation of the ribosomes carrying Phe-tRNA and AcPhe-tRNA with TI$_s$, TI$_u$ and GTP does not decrease the amount of AcPhe-tRNA that reacts with puromycin nor does such a treatment increase the amount of dipeptide. If, however, these ribosomes are incubated with TI$_s$, TI$_u$ and GTP in the presence of exogenous Phe-tRNA, additional Phe-tRNA is bound, and there is a decrease in the amount of AcPhe-tRNA that reacts with puromycin. Analysis of the products bound to the ribosomes indicates that the AcPhe-tRNA has interacted selectively with the exogenous Phe-tRNA to form dipeptide. There is no detectable conversion of the endogenous Phe-tRNA to dipeptide.

Erbe and Leder[22] found that in the presence of the dicodon messenger, AUGU$_3$, Phe-tRNA does not bind to ribosomes at low Mg^{2+} concentrations unless fMet-tRNA is bound to the ribosomes in the presence of initiation factors and GTP. Our results indicate that with poly U, enzymatic binding of Phe-tRNA to acceptor sites can occur at low concentrations of Mg^{2+} when donor sites are unoccupied, but the subsequent addition of AcPhe-tRNA to donor sites does not result in the formation of dipeptide. This observation suggests that binding of AcPhe-tRNA occurs on ribosome–poly U complexes different from those carrying the previously bound Phe-tRNA from complex II. This possibility is supported by the observation that in the presence of TI_s, TI_u and GTP, additional Phe-tRNA is bound to these ribosomes which specifically interacts with the AcPhe-tRNA to form dipeptide. If Phe-tRNA bound at the acceptor site of a ribosome complex prevents the binding of AcPhe-tRNA to the donor site, it is difficult to explain why the presence of the Phe-tRNA does not reduce the total amount of AcPhe-tRNA that is subsequently bound. The existence of populations of different ribosome–poly U complexes is quite likely.

---

* In an effort to establish a uniform nomenclature for the transfer factors, the following abbreviations are used:: TI$_s$, TI$_u$, and TII. These correspond to the designations FI$_s$, FI$_u$, and FII[9] and represent enzymatic activities comparable with the factors T$_s$, T$_u$, and G (Lucas-Lenard and Lipmann[11]) and S$_1$, S$_3$, and S$_2$ (Skoultchi *et al.*[7]).

Another possibility that cannot be disregarded is that binding occurs on the same ribosome without dipeptide formation. If this is the case, Phe-tRNA bound at the acceptor site does not interfere appreciably with either the binding of AcPhe-tRNA or the release to puromycin. Binding at the acceptor site without peptide bond formation is also observed when the GTP analogue 5′-guanylmethylene diphosphonate is substituted for GTP[12,13]. If binding occurs on the same ribosome, these data would suggest that the energy of the GTP moiety of the complex II is utilized for bringing the acceptor sites and donor sites into the proper juxtaposition for peptide bond formation and that unless the donor site is occupied at the time of binding (or shortly thereafter) the capacity for the formation of the peptide bond is lost on the release of P_i and $GDP–TI_u$[9,14] from the ribosome.

Whichever possibility is correct, this system furnishes a means of studying the prerequisites for and the mechanism of dipeptide formation. It is tempting to speculate that this system represents a model for a control mechanism that allows only nonfunctional reading of internal codons when the initiator codon has not been read.

Specific Antibodies to Triiodothyronine Hormone

WE have been able to stimulate the formation in rabbits of a very specific antibody against triiodothyronine (T_3) by injecting the animals with a condensation product of T_3 and succinyl poly-L-lysine. Antibodies against thyroxine (T_4) have been obtained by Clutton, Harington and Yuill[1] and by Churchill and Tapley[2] using conjugated hapten–protein antigens, but the use of natural proteins as carriers may be the reason for the rather low specificity of the resulting antibodies. We prepared succinylated poly-L-lysine by the method of Stason, Vallotton and Haber[3], and reacted it by carbodiimide condensation with the methyl ester of T_3. After saponification a highly specific antigen was obtained.

In a typical procedure, T_3 methyl ester hydrochloride (33 mg), succinylated poly-L-lysine (15 mg), 1-ethyl-3(3-dimethylaminopropyl)carbodiimide hydrochloride (30 mg) and triethylamine (5 mg) were dissolved in dioxane–water (1 : 1; 10 ml.). After being stirred in the dark for 24 h at room temperature, the solvent was evaporated in a vacuum and the methyl ester saponified with 0·1 M NaOH (3·0 ml.); after being washed with water, dioxane and ether–ethanol (75 : 25), 750 μg of the resulting compound in Freund's adjuvant (200 μl.) was injected into the toe-pads of rabbits. A similar subcutaneous injection was given 6 weeks later, and after a further 2 weeks blood was withdrawn from the treated and from normal rabbits. Incubation of dilutions of these sera together with $^{125}I-T_3$ revealed the presence of antibodies directed against T_3.

Table 1. RELATIVE CROSS-REACTIVITY WITH L-TRIIODOTHYRONINE OF THYROID HORMONE ANALOGUES AND OF L-LYSINE

Compound	Relative reactivity (arbitrary value if $L-T_3 = 100$)
$D-T_3$	90–100
$L-T_4$	2–5
$D-T_4$	2–5
3-Monoiodo-L-tyrosine	< 0·1
3,5-Diiodo-L-tyrosine	< 0·1
Deaminothyroxine	< 0·1
Triiodothyroacetic acid	~ 30
L-Lysine	< 0·1

Using the antibody as the saturable reagent, a radioimmunoassay technique for T_3 was developed. Dilutions of T_3 in 0·1 per cent albumin–barbitone were prepared yielding T_3 concentrations of 280, 140, 70, 35, 17·5 and 0 pg per 100 μl. They were placed into incubation tubes together with 20 μl. of $^{125}I-T_3$ (12 pg) and 50 μl. of antiserum (1 : 600 dilution) in albumin–barbitone buffer. After incubation at 4° C for 24 h, 50 μl. of a suspension of charcoal (100 mg per 20 ml.) and methyl-cellulose (100 mg per 20 ml.) in buffer was added. After mixing and standing for 5 min, the mixture was centrifuged for 15 min at 4° C. Radioactivity in both the supernatants (bound fractions) and the charcoal pellets (free fractions) was counted, together with that in the standards, on a two-channel 'Autogamma' counter, and the ratio of the activities was calculated.

Assays of the cross-reactivity of closely related substances are given in Table 1.

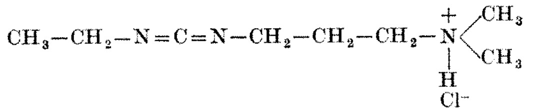
Biologically Active Antibodies to Histamine

It has been known for some time that peptides, amino-acids and proteins containing the substituents COOH and NH_2 can be linked together by the use of water soluble basic carbodiimides[1]. Goodfriend *et al.*[2] showed that linking the polypeptides of bradykinin and angiotensin with rabbit serum albumin (RSA) by the use of carbodiimides produced a complex which was highly antigenic. Subsequently Davis *et al.*[3] showed that the antibodies induced by the bradykinin–RSA complex were protective against the biological effects of bradykinin, and Oken *et al.*[4] obtained similar results with angiotensin. So far the use of carbodiimides has been confined to protein and peptide syntheses.

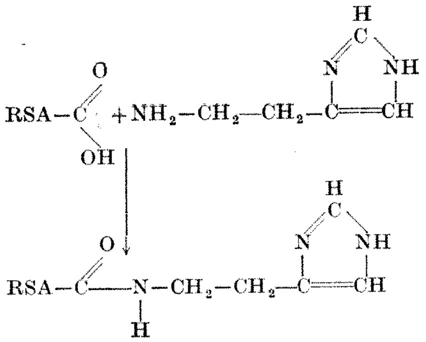
We have made a preliminary study to determine whether or not linkages between RSA and non-peptide compounds containing the NH_2 but not the COOH substituent could be made, and whether or not the resulting complex was antigenic. The compound chosen for the study was histamine, which was linked to RSA using the carbodiimide

1-ethyl-3-(3-dimethylaminopropyl) carbodiimide HCl



$$CH_3{-}CH_2{-}N{=}C{=}N{-}CH_2{-}CH_2{-}CH_2{-}\overset{+}{\underset{\substack{|\\ H\\ Cl^-}}{N}}\begin{matrix}CH_3\\ CH_3\end{matrix}$$

The most likely reaction is between the primary amine of histamine and a carboxyl group from the protein. The chemical reaction is shown as:



The resulting complex was used to immunize guinea-pigs using the immunizing regimen described for bradykinin[2,3] whereby a first immunizing dose is given in the pads of the paws with second and third immunizing doses given intradermally in the back at intervals of 21 days.

Dilutions of the serum which produced a reaction on Ouchterlony plates against the histamine–RSA complex varied between 1 : 16 and 1 : >256, with 80 per cent occurring at dilutions of 1 : 64 or greater. The ability of the antibodies in the serum to neutralize the biological effects of histamine was tested by making a LD_{50} mixture of histamine (0·19 mg/kg body weight for the guinea-pig) either with non-immune serum (control) or with immune serum (test) and injecting these intravenously into guinea-pigs.

Table 1. MODIFICATION OF LD_{50} DOSE OF HISTAMINE BY ANTIBODIES INDUCED BY AN ANTIGEN PRODUCED BY A COMPLEX OF HISTAMINE AND RABBIT SERUM ALBUMIN

			Reaction			
	None	Mild	Moderate	Severe	Death	Total
LD_{50} in non-immune serum						
No. of animals	0	6	4	3	11	24
Percentage	0	25	16	13	46	100
LD_{50} in immune serum						
No. of animals	2	22	6	0	3	33
Percentage	6	67	18	0	9	100

Table 1 shows that the LD_{50} intravenous dose of histamine made up with non-immune serum produced close to the expected 50 per cent death rate with 59 per cent of the animals in the severe reaction and death categories. On the other hand, the LD_{50} intravenous dose of histamine made up with immune serum produced only 9 per cent of animals in the severe reaction and death categories with 73 per cent of animals in the no reaction and mild reaction categories. This shift in distribution was statistically highly significant ($P < 0{\cdot}005$) using the χ^2 test for significance.

The presence of antibodies in actively immunized animals produced no obvious adverse effects in terms of changes in growth rate, overt behaviour or physical appearance. These results indicate that antibodies which neutralize histamine can be induced by an antigen resulting from covalently bonding histamine to a large protein molecule such as RSA.

Examination of "Species Specificity" of Avian Interferons

INTERFERON preparations usually show some degree of species specificity in their antiviral effects, exerting their greatest effect on growth of viruses in cells of the species which produced the interferon, and being less active or totally inactive in cells of other species[1-3]. Recent studies have shown that species specificity is far from absolute: certain human and primate interferons have proved active in rabbit cells[4]; the activity of monkey interferon in human cells was first noted by Isaacs *et al.*[5]; and cross-reactivity of human and monkey interferon systems at the level of the taxonomic family has been demonstrated[6]. Mouse serum interferon expresses one-twentieth of its mouse cell activity on other rodent cells[7].

These findings suggest that the closeness of the genetic relationship between two species may determine the ability of their interferons to exhibit heterologous activity. To examine this possibility, we have studied the reactivity of avian interferons from three orders of the class *Aves* on cells of closely and distantly related avian species.

Embryo fibroblasts from one-half term embryonated eggs were used, and interferons were produced either in eggs or in the cell cultures. Eggs were inoculated with influenza A–1 virus, strain WS–157. Allantoic fluid was harvested after 48 h incubation. Interferon was produced in cell culture by application of ultraviolet-inactivated Newcastle disease virus at a multiplicity of ten virus plaque forming units (pfu) per cell estimated before irradiation. Culture fluids were prepared after 25 h incubation at 37° C. All preparations were titrated to *p*H 2 with HCl and stored for 48 h at 4° C. After neutralization with NaOH solution, samples were centrifuged at 100,000*g* for 1·5 h. Supernatants were checked for the complete removal of virus by reinoculation into embryonated hens' eggs.

Interferon assays were done on monolayers of embryo fibroblasts in 60 mm Petri dishes. Two-fold dilutions of the samples were applied and left in contact with the cells for 20 h. The cells were than washed with balanced salts solution, and 50 to 80 pfu of vesicular stomatitis virus

Table 1. REACTIVITY OF GALLIFORM INTERFERONS*

NSE = No significant effect; — = Not done.

was applied. After adsorption for 1 h at 37° C, agar overlay was added. When plaques were well developed a second agar overlay containing 0·1 per cent 2-(*p*-iodophenyl)-3-(*p*-nitrophenyl)-5-phenyltetrazolium chloride (INT) (Aldrich Chemical Company)[8] was added and the plates incubated 8 h or longer—until the living cells reduced the tetrazolium salt to a purple-red formazan and plaques could be counted. Titres of viral inhibitor are expressed as the reciprocal of the dilution of the sample which reduced the plaque count to 50 per cent of that of the controls.

Table 1 shows the results of assaying interferons from various species of the Galliformes. The titres on homologous cells are in italic type. Considerable interspecific activity was found between interferons and cells of the six representatives of the Galliformes. No effect was found when any of the galliform interferons were tested on cells of species from the orders Anseriformes or Columbiformes. Certain interferons, notably quail, displayed a "one way" activity similar to that observed by Desmyter *et al.*[4]. Quail interferon is inactive in all except its homologous cells, but all other galliform interferons are highly active in quail cells.

Table 2 shows the results obtained for interferons from the three anseriform and one columbiform species. Preparations from the Pekin duck, mallard duck, and goose protected homologous cells and cells of the other two anseriform species to some extent, but the other cells not at all.

Tests on several of the heterologously active viral inhibitors have shown that they qualify as interferons by meeting the generally accepted requirements[2,11].

These studies show that degree of genetic relatedness between avian species can influence the ability of their interferons to exhibit heterologous activity. "Order specificity" is indicated: cells and interferon preparations from members of one avian order can interact to some extent with others of their order, in agreement with the conclusions of Bucknall[6] in his study of primate interferons.

It is not possible to predict interactions by phylogenetic relatedness. Chukar partridge interferon was active in turkey cells but inactive in chick. The chukar partridge and chicken are both members of the same family (Phasianidae), but the turkey is classed in a separate family (Meleagrididae). Similarly, the pheasant and chicken are considered more closely related, in currently accepted classification schemes, than any of the other galliform birds studied, yet chick interferon was totally inactive in pheasant cells. Why bob-white quail cells exhibit a notably increased response to chick, turkey and guinea-fowl interferon, but quail interferon is totally inactive in all other galliform cells, is not yet explained. This may be a question involving cell receptors for interferon. Investigations of "one way" reactivities such as this may answer some basic questions on how and whether externally applied interferon enters cells.

Synthetic Polyanions protect Mice against Intracellular Bacterial Infection

A NUMBER of synthetic polyanions stimulate interferon production[1-7] and these materials are active against infection with viruses and also with parasites of a more complex nature[8-12]. Mice inoculated intraperitoneally with pyran, a random copolymer of divinyl ether and maleic acid anhydride, are resistant to an ordinarily lethal challenge of mengo virus[7]. Such antiviral resistance persists for as long as 60 days in spite of the absence of measurable levels of interferon in the sera of the mice after 4 to 6 days[7,13]. These polyanions modify a number of host defence mechanisms including delayed hypersensitivity[14], antibody response[15] and the number of circulating white blood cells[16]. In view of the suggestion that a common mechanism of host resistance to intracellular pathogens may exist[17], we were interested to determine if the long term resistance against viral challenge observed following administration of such polymers may also be extended to intracellular bacterial infection. In these studies, three anionic polymers*, pyran copolymer, polyacrylic acid and the double stranded synthetic ribonucleic acid poly I·poly C, each conferred resistance to *Listeria monocytogenes* infection in mice.

Pyran conferred resistance to listeria when inoculated by either subcutaneous or intraperitoneal routes. Swiss–Webster female mice, used in all studies, were inoculated with pyran and challenged at varying times thereafter. Mice challenged with listeria intraperitoneally 18 h after receiving pyran by the same route did not manifest resistance and died earlier than control animals. By 4 days, decreased mortality and/or extension of life was noted and this resistance persisted for 2 months, but at a lower level than noted at 1 month (Fig. 1*A*). Mice challenged with listeria intraperitoneally after subcutaneous injection of pyran were also protected (Fig. 1*B*). Mice challenged with listeria subcutaneously showed protection if challenged with listeria at 18 h, 8 days, 1 month and 2 months after receiving pyran intraperitoneally but not at 4 or 6 months (not illustrated). With this combination of inoculation routes, mice which received 50 mg/kg were better protected at 18 h and 8 days than those which received 125 mg/kg, suggesting that the higher doses were associated with a toxicity which is apparent when the bacterial challenge is close to polymer administration. Preliminary experiments indicated, however, that 125 mg/kg gave more protection at later challenge times.

The relationship of the resistance conferred by pyran to its high density of negative charges was tested using another anionic polymer and its amide. Blocking of the negative charges resulted in a loss of the polymer's ability to confer resistance. Whereas mice which had been injected with polyacrylic acid 1 month previously were remarkably resistant to listeria challenge, those inoculated with polyacrylamide died similarly to control mice (Fig. 1*C*).

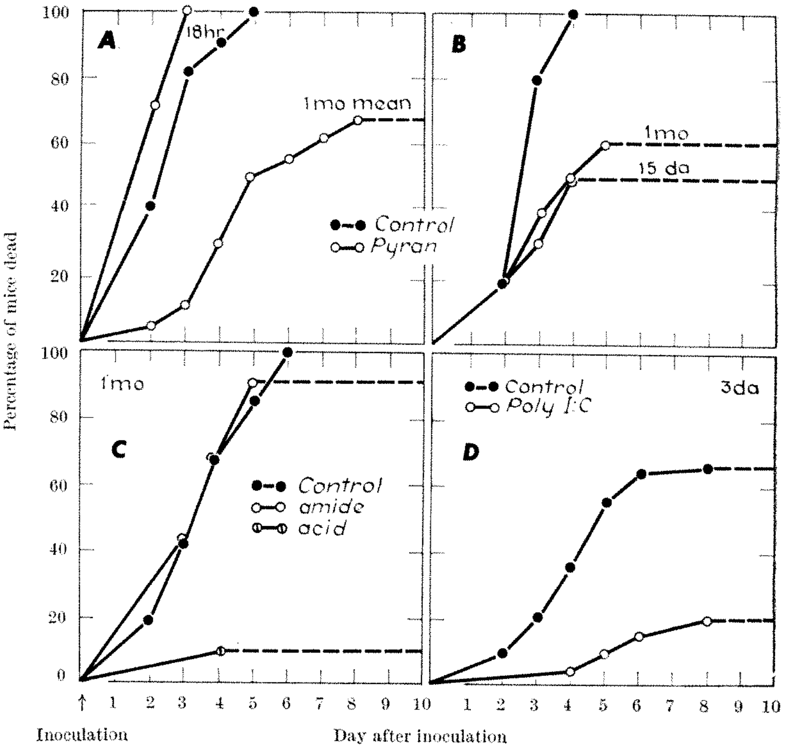

Fig. 1. Effect of anionic polymers on resistance in mice to challenge with *Listeria monocytogenes*. The strain of listeria and preparation of the inoculum were as previously described[17]. Results in *A*, *B* and *C* represent groups of ten mice and in *D* of twenty mice. The time periods represent the interval between injection of the polymer and inoculation of listeria challenge. *A*, 125 mg/kg pyran intraperitoneally and 4×10^7 listeria intraperitoneally; *B*, 125 mg/kg pyran subcutaneously and 4×10^7 listeria intraperitoneally; *C*, 16 mg/kg of polyacrylic acid or of polyacrylamide intraperitoneally and $1{\cdot}5 \times 10^7$ listeria; *D*, 1 mg/kg poly I·poly C intraperitoneally and 9×10^6 listeria intraperitoneally. The results for 1 month in *A* represent the average of results from five separate experiments. Dashed line signifies fraction of mice surviving to 1 month after bacterial challenge.

Poly I·poly C was active in the same experimental model in conferring resistance to listeria, but for a shorter period of time than noted with pyran. Mice were inoculated intraperitoneally with either poly I·poly C or 0·15 M NaCl (the diluent for the poly I·poly C) and challenged with listeria intraperitoneally 18 h, 3 days, 8 days and 14 days thereafter. As observed with pyran, there was early death in mice challenged 18 h after receiving poly I·poly C when compared with controls. At 3 (Fig. 1*D*), 8 and 14 days, protection was apparent in the animals which received the double-stranded polyribonucleotide.

Studies to determine whether resistance might be partially attributable to enhanced reticuloendothelial clearance revealed a significant difference in clearance of carbon between normal mice and pyran treated mice, which were resistant to listeria challenge. The methods used[18] were adapted from the work of Biozzi *et al.*[19]. Carbon particles were injected intravenously into twelve normal and eleven pyran mice (inoculated 30 days earlier with 125 mg/kg pyran). The concentrations of carbon in serial samples of blood were determined spectrophotometrically at 650 nm. Clearance rates (log of the carbon concentration plotted against time) were linear for all animals and the average slope, *K*, was 0·037 (0·026–0·039) for control animals and 0·078 (0·054–0·111) for the pyran treated mice.

Resistance against phylogenetically unrelated organisms has been associated with "activated" macrophages[17]. Because pyran confers resistance to viruses[7], protozoa (in our unpublished studies, when groups of twenty mice were challenged intraperitoneally or subcutaneously with strain C56 of *Toxoplasma gondii* at 18 h and 2 months following intraperitoneal pyran inoculation, decrease in mortality and prolongation of life were noted in groups of pyran treated animals compared with diluent inoculated controls), and bacteria, we investigated whether macrophages from the pyran treated mice were resistant to challenge with listeria *in vitro*. The methods were essentially those previously described[18]. Peritoneal macrophages from mice inoculated intraperitoneally with pyran were resistant to listeria challenge. Whereas control cell monolayers and monolayers from pyran treated mice had comparable numbers of cells per high power field at 1 h after infection, there were more cells infected and more bacteria per cell in the pyran monolayers at that time. At 6 h following infection (in one representative experiment of the eight performed) (Fig. 2), there was a 30 per cent reduction in cells in the normal cell monolayers, but the pyran cell monolayers remained intact. During this time there was an increase in percentage of normal cells infected from 23 per cent at 1 h to 51 per cent at 6 h, but a decrease in the percentage of pyran cells infected from 36 per cent at 1 h to 24 per cent at 6 h. The numbers of stainable bacteria per cell during this time increased in normal cells but remained the same in pyran treated cells.

Similar experiments were performed using macrophages obtained from mice inoculated intraperitoneally 18 h or 3 days earlier with 1 mg/kg of either poly I·poly C, poly I, poly C or diluent. Poly I·poly C and poly I had essentially the same action as pyran in the 18 h mice, but no protection was afforded by poly C. No difference was noted between control cells and those from mice treated with polynucleotides 3 days earlier.

---

* Pyran copolymer (mol. wt. 31,000) was obtained through the courtesy of Dr W. H. Wood, of the National Service Center, Drug Development Branch, Cancer Chemotherapy, United States Public Health Service; and polyacrylamide (S-692, mol. wt. 60,000–70,000) and polyacrylic acids (T-132, mol. wt. 60,000–70,000) synthesized by Monsanto, St Louis, Missouri, and obtained from Dr William Regelson, Division of Oncology, Medical College of Virginia, Richmond, Virginia. Poly I·poly C was prepared in our laboratory by annealing homopolyribonucleotides purchased from Miles Laboratories, Elkhart, Indiana.

Identification of the mechanisms of these effects may have useful practical consequences in the control of various intracellular infections in man. The prolonged protective effect of pyran and poly I·poly C in these and other studies[7] suggests mechanisms not involving interferon, because circulating interferon disappears much earlier. The enhanced reticuloendothelial clearance of carbon particles observed in pyran treated animals may not necessarily be critical, for a remarkable resistance of protozoal-infected mice to listeria[17] and mengo virus[20,21] has been observed in the absence of enhanced reticuloendothelial clearance[18]. The "activated" character of macrophages obtained from mice injected with pyran and poly I·poly C suggests a role for these cells in protection against *in vivo* challenge with listeria. To evaluate the contribution of interferon, preliminary experiments were performed using macrophages treated with interferon at levels which protected other cell lines against TRIC agents[10] and *Toxoplasma gondii*[12] as well as viruses. No protection was noted in the interferon treated monolayers. The enhanced antibody production noted following administration of these polymers[15] is not a likely cause of the resistance to listeria infection because most workers[22] agree that conventional circulating antibody does not contribute significantly to host resistance against this intracellular pathogen.

Resistance to intracellular bacteria has been closely related to the presence of delayed hypersensitivity[23]; the resistance conferred by these polymers may be related to their ability to enhance cell mediated defence mechanisms against foreign antigens[14]. The critical antibacterial mechanism(s) operative in this system may be similar to those that mediate the anti-protozoan and anti-tumour effects of these polymers[11,24,25]. Other recent data (ref. 26 and personal communication from M. Weinstein, J. Waitz and P. Came) indicate protective effects with polyanions against other bacterial species in mice.

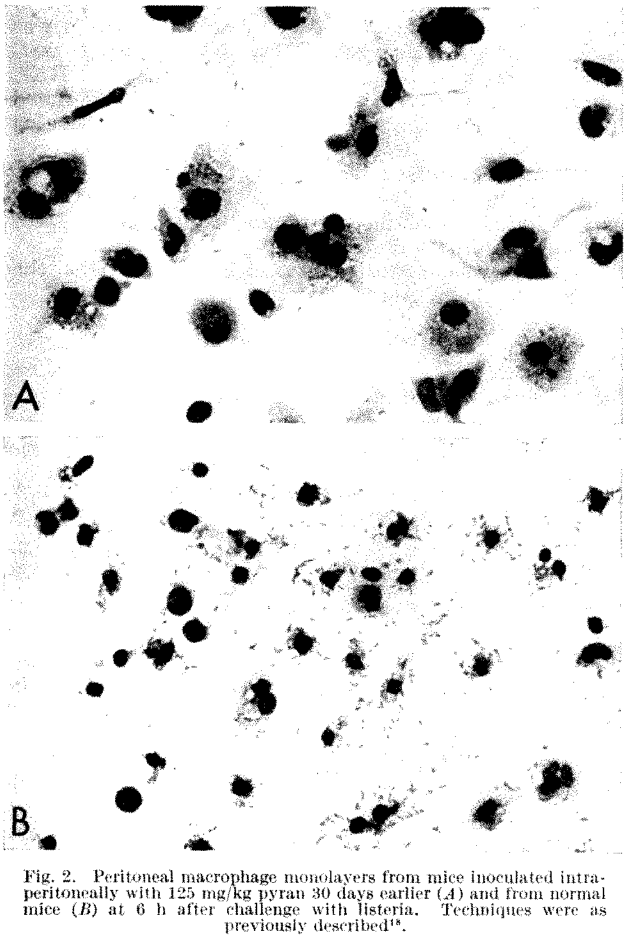

Fig. 2. Peritoneal macrophage monolayers from mice inoculated intraperitoneally with 125 mg/kg pyran 30 days earlier (*A*) and from normal mice (*B*) at 6 h after challenge with listeria. Techniques were as previously described[18].

Induction of Resistance to Tobacco Mosaic Virus by Poly I·poly C in Plants

PREVIOUSLY it was reported from our laboratory that when yeast RNA was injected intercellularly into leaves of *Nicotiana tabacum* L. Samsun NN, induced resistance developed from the third day on[1]. Interference was highest when plants were inoculated with tobacco mosaic virus (TMV) 5–6 days after RNA was injected at a concentration of 5 mg/ml., and remained high even after 20 days. In the resistant tissue, TMV lesion numbers decreased by 80–90 per cent, compared with those developing in water-injected control tissues. The development of resistance was inhibited if actinomycin *D* was applied shortly after the induction with yeast RNA.

These results were confirmed with yeast RNA and with RNA isolated from plants different from the test species (foreign RNA), whereas the resistance response was not elicited by RNA isolated from plants of the test species[2]. A similarity between yeast RNA induced resistance in plants and interference in animal virology mediated through interferon was suggested[1,2].

Recently, it was reported that double-stranded RNA, polyinosinic-polycytidylic acid (poly I·poly C), is capable of inducing animal cells to produce large amounts of interferon and high levels of resistance to virus infection[3,4]. We were therefore interested to see if poly I·poly C would induce resistance against viruses in plants.

Tobacco NN and *Datura stramonium* L. plants were grown in a screened greenhouse, and transferred before use to a greenhouse chamber set at 20° C, as described previously[1]. Poly I and poly C homopolymers (Schwarz BioResearch or Miles Laboratories) were dissolved in small amounts of sterile double-distilled water and then suspended in 0·15 M NaCl or KCl. Solutions of poly I and poly C were mixed in equimolar concentrations. Complex formation, as determined by hypochromic effect, developed within a few minutes after mixing. The poly I·poly C solution was then diluted to the appropriate concentrations of poly I·poly C and salt, and persistence of the complex was again checked spectrophotometrically. Poly I·poly C, or sterile salt solution as a control, was injected intercellularly into the opposite halves of tobacco NN or *D. stramonium* leaves[1,5]. The leaves were then washed carefully with tap water. For each experiment the two lower leaves of at least three tobacco NN or *D. stramonium* plants were used. In additional control plants the suspending medium was injected into one side of the leaves, whereas the opposite sides remained uninjected. Injections of poly I·poly C (50 μg/ml.) in salt solutions, or salt solutions alone at concentrations between 0·03 and 0·15 M, did not damage the leaves. Occasionally, with the higher salt concentrations, wilting was observed immediately after injection, but the leaves recovered completely within hours. About 0·6–0·9 ml. and 0·3–0·6 ml. fluid was injected into each half leaf of tobacco NN or *D. stramonium* respectively. After varying intervals the whole leaf was inoculated with TMV (5 μg/ml.). Lesions were counted after 7 days and the interference percentage induced by poly I·poly C was calculated. The results were analysed by the "sign test"[6].

Table 1. DEVELOPMENT OF INDUCED INTERFERENCE AFTER INJECTION OF POLY I·POLY C INTO HALF-LEAVES OF TOBACCO NN AND *D. stramonium*

Host	Time between poly I·poly C injection and inoculation with TMV	Lesions* per half-leaf injected with		Interference (per cent)
		Poly I·poly C	Control medium	
Tobacco NN	5–7 h	321	337	4
	24 h	446	697	36 ‡
	2 days	122	238	49 ‡
	3 days	105	169	38 ‡
	4 days	157	213	26 †
D. stramonium	5–7 h	104	113	5
	24 h	224	224	0
	2 days	130	245	47 ‡
	3 days	144	224	36 †
	4 days	226	357	37 ‡
	5 days	64	127	50 ‡
	6 days	145	376	61 ‡

* Average of counts from three experiments, six leaves each.
† Significant at the 5 per cent level.
‡ Significant at the 1 per cent level.

Results, averages from three experiments, are summarized in Table 1. When tobacco NN leaves were inoculated with TMV 5–7 h after poly I·poly C injection, no difference in lesion number between poly I·poly C treated and control half-leaves was observed. If, however, TMV was inoculated 24 and 48 h after poly I·poly C injection, the lesion number on the poly I·poly C injected half-leaves was reduced by 36 and 49 per cent, respectively. In eight additional experiments, when TMV was inoculated 48 h after poly I·poly C injection (in salt concentrations between 0·05–0·15 M), significant reductions (at the 0·01 level) in lesion number were always observed. The variation in the number of lesions in the control half-leaves, especially the increase noted when tobacco NN leaves were inoculated 24 h after injection, does not seem to be significant. It seems to represent a statistical effect caused by variations in sensitivity of plants in different experiments. Occasionally, the reduction in lesion numbers on the poly I·poly C injected leaves reached 70–80 per cent. This was accompanied by a considerable reduction in lesion size. Generally, after 4 days the degree of interference induced in tobacco, by this concentration of poly I·poly C, decreased. In the majority of experiments no significant effects of injecting salt solutions alone, compared with non-injected controls, were observed. Those few experiments in which salt solution affected lesion number by more than 15 per cent were not included in the evaluation of the results obtained by poly I·poly C. Preliminary experiments with lower concentrations of poly I·poly C, that is, 15 and 25 μg/ml., were generally less effective; and concentrations of 100 and 200 μg/ml. did not result in higher levels of interference than those obtained with 50 μg/ml.

Similar results were observed in *D. stramonium* leaves injected with poly I·poly C (50 μg/ml.) in 0·037 M or 0·05 M KCl. Interference was highest, however, when plants were inoculated with TMV 5–6 days after poly I·poly C treatment (Table 1).

Inoculating TMV in the presence of 60 and 200 μg/ml. poly I·poly C did not inhibit lesions, and no interference developed in tobacco leaves if poly I or poly C (50 μg/ml. in 0·075 M NaCl) alone was injected.

These results suggest that the multistranded synthetic polynucleotide complex poly I·poly C activates an interference mechanism in plant hosts, because a time interval is necessary for the development of the resistance, and because no competitive inhibition was observed even at concentrations that were three times higher than those necessary for inducing interference. This induction of interference by poly I·poly C in tobacco NN leaves was less effective than by yeast RNA. Poly I·poly C was, however, active at 50 μg/ml., whereas with yeast RNA 5 mg/ml. was required for induction. It should be noted that for the induction of resistance, the double-stranded polynucleotide was necessary, and no interference developed if single-stranded poly I or poly C at these concentrations was applied. Similar results have been reported for the induction of interferon and resistance to virus infection in animal cells[3,4].

Increase in Antiviral Activity of Polynucleotides by Thermal Activation

LIMITED preincubation (5 min to 2 h) at 37° C was found to increase the activity of several synthetic polynucleotides in producing cellular resistance to virus infection *in vitro* by several orders of magnitude, and to a lesser extent, induction of interferon *in vitro* and *in vivo*. The thermal activating effect was observed for both alternating copolymers and homopolymer pairs of either RNA or DNA types, but was most marked with the alternating polyribonucleotides such as poly A·poly U and poly I·poly C. Our findings might help to explain the variable biological activity of polynucleotides according to the way they are processed before testing.

Polynucleotides were obtained from different sources: the alternating copolymers poly (I–C), poly (G–C), poly d (I–C) and poly d (G–C) were prepared by one of us (R. D. W.); poly d (A–T) was kindly supplied by Dr I. R. Lehman (Stanford, California). The random copolymer poly (A,U) (1 : 1) was purchased from Miles Laboratories, Elkart, Indiana, and the alternating copolymer poly (A–U) from Biopolymers, Pinebrook, New Jersey. The homopolymer pairs poly I·poly C and poly A·poly U were prepared by annealing the individual homopolymers as described previously[1]. Poly I and poly C were purchased from P–L Biochemicals, Milwaukee, Wisconsin, and poly A and poly U from Miles Laboratories. Concentrations of the polymers were determined spectrophotometrically[1]. They were dissolved in normal saline, stored at –20° C but dialysed at 4° C against minimal Eagle's medium (MEM) before use.

Interferon production and cellular resistance to bovine vesicular stomatitis virus (Indiana strain) were determined in human skin fibroblasts as described previously[1]. Interferon production was also measured *in vivo* (Swiss–Webster mice, 15–20 g) after intravenous injection.

Table 1. CELLULAR RESISTANCE TO VESICULAR STOMATITIS VIRUS IN HUMAN SKIN FIBROBLASTS

	Minimal inhibitory concentration* (μg/ml.)	
Polynucleotide	Preincubation† (2 h) at 0° C	at 37° C
Poly (A–U)	> 1	0·000004
Poly (I–C)	> 10	0·0004
Poly (G–C)	> 10	0·001
Poly A·poly U	0·4	0·01
Poly I·poly C	0·004	0·00004
Poly d (A–T)	⩾ 10	0·01
Poly d (I–C)	⩾ 10	0·04
Poly d (G–C)	⩾ 10	0·1

* Concentration of polymer required to reduce virus plaque formation by 50 per cent.

† 0·15 M Na^+, pH 7·0–7·5 (normal saline, phosphate buffered saline or MEM). Poly (A–U), poly A·poly U and poly I·poly C were preincubated at 1·6 μg/ml., other polymers at 16 μg/ml. All incubations were performed in waterbaths at the indicated temperatures. Samples were further diluted in either precooled (0° C) or prewarmed (37° C) MEM and the dilutions applied to the cell monolayers immediately.

Preincubation at 37° C, compared with 0° C, rendered all polynucleotides, including poly I·poly C, significantly more active in reducing virus plaque formation in human cells, regardless of the medium in which the incubation was carried out (normal saline, phosphate buffered saline or MEM) (Table 1). The antiviral activities of the polydeoxyribonucleotides, which have repeatedly been reported to be low, or non-existent[2-5], were increased after heating at 37° C to values corresponding to those for the unheated poly A·poly U and poly I·poly C. Of all polymers tested, poly (A–U) exhibited the greatest change in antiviral activity. A 5 min incubation at 37° C was sufficient to increase the activity of poly (A–U) by more than 10^6 times. Incubation at 32° C or 56° C was as efficient as incubation at 37° C but there was no activation when poly (A–U) was kept at 25° C. Addition of 10^{-3} M EDTA following the 37° C incubation step or rapid cooling to 0° C (by immersion in solid CO_2–ethanol) reversed the activating effect, whereas slow cooling (by making dilutions in MEM equilibrated at 25° C) did not. Heating poly (A–U) to 90° C (well above its melting temperature[6]), followed by rapid cooling to 0° C, destroyed antiviral activity. Subsequent incubation at 37° C, however, re-established the increased activity. The hypothesis that the activated state of poly (A–U) depends largely on its capacity to form a rigid double helical structure is further supported by findings with the not strictly alternating copolymer poly (A,U). In this copolymer the random distribution of uridine and adenosine does not allow proper base pairing or the formation of a rigid rod-like helical structure, and even after preincubation at 37° C this polymer was devoid of activity at the highest concentration tested (10 μg/ml.).

Preincubation of poly (A–U) and poly (I–C) also increased their interferon inducing capacity *in vitro* (human skin fibroblasts) and *in vivo* (mice) (Table 2), but to a lesser extent than expected from their increased ability to confer cellular resistance to virus infection *in vitro* (Table 1). The homopolymer pair poly A·poly U were not activated and poly I·poly C were only minimally activated when tested for interferon induction either *in vitro* or *in vivo* (Table 2).

Table 2. INTERFERON PRODUCTION

	Interferon units			
	Human skin fibroblasts* (units/4 ml. culture fluid)		Mice† (units/4 ml. serum)	
Polynucleotide	Preincubation‡ (2 h) at 0° C	at 37° C	Preincubation‡ (2 h) at 0° C	at 37° C
Poly (A–U)	4	20	12	24
Poly (I–C)	2	18	15	42
Poly A·poly U	4	3	175	145
Poly I·poly C	10	14	1,310	2,750

* From 3 to 8 h after exposure of confluent cell monolayers in 60 mm Petri dishes to 20 μg of poly (A–U), 30 μg of poly (I–C), 200 μg of poly A·poly U and 20 μg of poly I·poly C in 1 ml. of MEM. Polymers were removed after 3 h incubation; cells exhaustively washed with MEM and further incubated with 4 ml. of MEM per Petri dish.

† 2 h after intravenous injection of 8 μg of poly (A–U), 20 μg of poly (I–C), 100 μg of poly A·poly U and 1 μg of poly I·poly C in 0·5 ml. MEM.

‡ All samples were preincubated in MEM at the given concentrations and applied to the cell monolayers or injected into animals immediately after.

Thus heating to 37° C must promote fundamental alterations in the secondary structure of polynucleotides (particularly alternating polynucleotides) which lead to increased biological activity. Studies to examine the relationship between the increased antiviral activity of preheated polynucleotides and changes in their physical properties and/or sensitivity to exo and endonucleases will be reported elsewhere (our unpublished results).

All polynucleotides tested are capable of forming a double-stranded structure and it is likely that moderate heating increased their antiviral activity by stabilizing their secondary double-stranded structure[1]. This stabilization may have been achieved through movement of one strand relative to its complementary strand[7], which might unite interrupted helices, take up loose, unpaired ends and debranch branched[8,9] structures, thereby reducing the number of unpaired regions.

The final antiviral activity of the thermally activated copolymers poly (A–U) and poly (I–C) was similar to the activity of their thiophosphate analogues, as measured by vesicular stomatitis virus plaque reduction in human skin fibroblasts (ref. 10 and unpublished results of E. de C., F. Eckstein, H. Sternbach and T. C. M.). In terms of interferon production *in vitro* and *in vivo*, however, substitution of thiophosphate for phosphate groups proved much more effective than thermal activation; an average of two to three-fold increase of interferon production was observed for the preheated poly (A–U) and poly (I–C) compared with a twenty to forty-fold increase for their thiophosphate analogues (ref. 10 and unpublished results of E. de C., F. Eckstein, H. Sternbach and T. C. M.). Heating of the thiophosphate analogues of poly (A–U) and poly (I–C) did not cause significant shifts in activity (unpublished results of E. de C., F. Eckstein, H. Sternbach and T. C. M.). Incubation at 37° C and substitution of thiophosphate for phosphate may both lead to enhanced antiviral effect through similar mechanisms or changes in molecular configuration. The heat-induced configurational changes are likely to be more reversible than the changes induced by substituting thiophosphate for phosphate, however, and this may explain the higher activity of the thiophosphates over the heated polymers *in vivo*.

Anti HL-A2 Inhibitor in Normal Human Serum

THE finding that allogeneic pig liver transplants frequently survive for a significantly prolonged period of time even without immunosuppression has led to a new line of research[1,2]. Calne and his colleagues have shown that the recipient of an allogeneic liver transplant showed partial tolerance towards kidney, and to a lesser extent towards skin transplants, when these were obtained from the same animal as was the liver.

Control experiments indicated that their findings could best be explained by assuming that the liver transplants had induced a state of (partial) specific immunotolerance. Preliminary findings indicate that similar phenomena were observed in the rhesus monkey[3]. If one assumes that the liver transplant induces a state of specific tolerance in the recipient, one could postulate two possible mechanisms for this. First, a tolerance may be established towards the transplant by the lymphocytes. Because this tolerance is not found in the case of kidney and heart transplants, the liver must be capable of inducing a tolerance. Second, the liver may excrete a substance which induces tolerance. Because the tolerance is specific for the individual, the most probable substance responsible could be a soluble HL-A antigen product (or its equivalent in other species)[3]. In that case, one would expect to find HL-A substances in serum or plasma. We describe findings which confirm this hypothesis.

Normal sera, either fresh or stored at 4° C or $-20°$ C, were used. In a few experiments oxalate plasma free of platelets, or sera and plasma, fractionated with either starch block electrophoresis or gel filtration were used. A strong monospecific anti HL-A2 serum (3990) was used throughout. The serum had a titre of about 1 in 32. Specified volumes of sera or plasma, or of fractions of these obtained by 'Sephadex' gel filtration or starch block electrophoresis, were mixed with a volume of the anti HL-A2 serum, incubated in a 37° C water bath for 60 min and thereafter at 4° C for another 60 min. One ml. of this mixture was then tested against 1 µl. HL-A2 positive cells in the microcytotoxicity test described by Kissmeyer-Nielsen[4].

When 0·01 ml. of anti HL-A2 was mixed with 0·20 ml., 0·25 ml. and 0·30 ml. of fresh HL-A2 positive serum and each of these fractions was then tested for residual anti HL-A2 activity, a consistently negative result was obtained only when one part of this particular anti HL-A2 serum was mixed with thirty parts of serum from an HL-A2 positive donor (Table 1). When the donor was HL-A2 negative, clearcut anti HL-A2 activity was always demonstrable, even at this dilution (thirty parts serum from an HL-A2 negative donor mixed with one part anti HL-A2 serum 3990).

Table 1. DETERMINATION OF THE OPTIMAL CONDITIONS FOR THE INHIBITION TEST

HL-A2 type of serum donor	Cytotoxicity with serum volume: 0·20 ml.	0·25 ml.	0·30 ml.
1 positive	+ +	+ +	–
2 positive	+ +	+	–
3 positive	+ +	(+)	–
4 negative	+ +	+ +	+ +
5 negative	+ + +	+ +	+
6 negative	+ + +	+ + +	+ + +

Different amounts of serum to be studied for HL-A2 inhibitory activity were mixed with 0·01 ml. of anti HL-A2 serum 3990, incubated first in a 37° C waterbath for 60 min and then at 4° C for another 60 min. One µl. of this mixture was tested against HL-A2 positive lymphocytes in the microcytotoxicity test[4]. When 0·30 ml. of serum was used for the inhibition test a distinction between sera from HL-A2 positive and negative donors was possible.

Table 2. HL-A2 ACTIVITY IN NORMAL HUMAN SERUM

Sera from HL-A2 positive donors: Donor No.	Storage (days)	Cytotoxicity results	Sera from HL-A2 negative donors: Donor No.	Storage (days)	Cytotoxicity results
1	0	–	25	0	+ +
2	0	–	26	0	+ +
3	0	–	27	0	+ +
4	0	–	28	0	+ +
5	0	–	29	0	+ + +
6	0	–			
7	0	–			
8	0	–			
9	0	–			
10	0	–			
11	0	–			
12	0	–			
13	0	–			
14	0	–			
15	7	–	30	7	+ +
16	7	–	31	7	+ +
17	7	–			
18	30	–	32	30	+ +
19	30	–	33	30	+
20	30	+	34	30	+ + +
21	30	+			
22	30	+			
23	30	+			
24	30	+			

0·30 ml. serum to be tested was mixed with 0·01 ml. anti HL-A2 3990, incubated first at 37° C for 60 min and then at 4° C for another hour. Then 1 µl. of the mixture was tested against 1 µl. of HL-A2 positive lymphocytes in the microcytotoxicity test. A negative reaction implies that inhibitory activity was present; a positive reaction, that it was not present.

A larger number of sera from HL-A2 positive and negative donors was studied (Table 2). It was observed that, in the conditions of the test, sera from HL-A2 negative donors were not able to inhibit the anti HL-A2 activity of the antiserum; sera from most HL-A2 positive donors did so, however. Although in some cases the inhibitory activity was present after prolonged storage at $-20°$ C, the results with fresh serum seemed to be the most consistent.

Similar findings were obtained with oxalate plasma free of platelets, which makes it most unlikely that the inhibitory activity is the result of antigen or hapten release *in vitro* caused by platelet disintegration during clotting. Sera from HL-A2 negative and positive donors are clearly distinguishable only over a narrow range of serum dilutions (Table 1). These dilutions are volumetric. It is thus unlikely—also considering the consistency of our findings—that our observations are the result of a serological artefact.

Residual anti HL-A2 activity after the inhibition test was determined in the microcytotoxicity test described

The new Monroe 820 Calculator

The Monroe 820 introduces a brand new generation in electronic calculators. Smaller, lighter and much more compact, thanks to integrated microcircuits. Simple to operate, priced to fit your budget. Using only four keys more than an adding machine to handle every business calculation in milliseconds.

You can do arithmetic operations in any sequence and there are a host of advanced features including automatic constant multiplier and divisor, automatic decimal point and roundoff, and automatic squaring.

Fourteen digit answers appear sharp and clear in large numerals on the non-glare display screen – plus the running total.

The 820 is ready for work the instant it's switched on and there's no need to clear the calculator.

It all happens in complete silence.

CLYDE MANWELL and C. M. ANN BAKER

Molecular Biology and the Origin of Species:
Heterosis, Protein Polymorphism and Animal Breeding

This book is a review of a number of aspects of the genetics of populations, aimed primarily but not exclusively at the biochemical level. A balanced review of the evidence refutes the frequently held belief in constant heterozygote superiority, the **heterosis mystique.** The new theory provides an explanation for a number of taxonomic and zoogeographical observations.

The book is intended for both biologists and biochemists, including those whose interests are in medicine or agriculture.

by Kissmeyer-Nielsen; human serum was used as a source of complement. Our studies indicate the importance of using human sera from donors who do not carry the antigen under study as a source of complement.

The results obtained by starch block electrophoresis were sometimes erratic. Although a number of sera from HL-A2 positive donors showed consistent and reproducible inhibitory activity of their albumin fractions, others did not.

These preliminary findings make it highly probable that HL-A2 haptens or antigens are present in the plasma and serum of man. Although it is tempting to speculate about a possible correlation between Calne's experiments and our results, it should be stressed that nothing is known at present about the possible biological implications of our findings, if any. Whether similar substances are present in pig serum is also unknown. The study of other antigens has been hindered by the lack of high-titre monospecific antisera. The possible biological and clinical implications of these findings, especially for the induction of specific tolerance, are now the subject of further study.

We thank Dr M. C. Botha, Cape Town, for the gift of serum 3990. This work was supported in part by grants from the Institute for Radiopathology and Radiation Protection, the Netherlands Organization for the Advancement of Pure Research (ZWO), the Netherlands Organization for Applied Scientific Research (TNO), the World Health Organization and the Whitehall Foundation.

Xg Locus: Failure to detect Inactivation in Females with Chronic Myelocytic Leukaemia

THE inactive-*X* hypothesis states that only one of the two *X* chromosomes in each somatic cell of adult mammalian females is genetically active. The initial event in early embryogenesis which determines whether the paternal or the maternal *X* chromosome will remain active in any given cell is presumably random; once made, the choice is fixed for that cell and for all its descendants[1-4]. Although this type of inactivation has been demonstrated in man for a number of *X*-linked loci[5], it is not known whether the entire *X* chromosome is inactivated.

The evidence is particularly conflicting for the *X*-linked locus determining the red cell antigen, Xg^a. The inactive-*X* hypothesis predicts that the red cells in an Xg^a/Xg heterozygote should consist of a mixture of Xg(a+) and Xg(a−) cells. In normal females, however, it has not been possible to demonstrate a mixture of this kind in association with the Xg^a/Xg genotype[6,7]. On the other hand, such mosaicism was reported in a family with *X*-linked anaemia, suggesting that the Xg locus does undergo inactivation[8]. Thus the question remains unresolved.

An alternative approach to this problem involves the study of a clone of red cells derived from a single cell. If random fixed inactivation does occur at the Xg locus, one would expect that in Xg^a/Xg heterozygotes, the red cells of which were derived from a single precursor cell, the phenotype would be either Xg(a+) or Xg(a−) depending on which *X* chromosome was active in that single precursor cell. Thus in contrast to normal heterozygotes, all of whom have the Xg(a+) phenotype, only half of the heterozygotes with clonally derived red cells would be Xg(a+).

In this study, patients with chronic myelocytic leukaemia (CML) were used as the source of clonal red cells. Cytogenetic and genetic evidence support a clonal origin of these red cells. For example, patients with CML usually have a partial deletion of a *G*-group chromosome in their myelogenous cells[9]. This so-called Philadelphia[1] (Ph[1]) chromosome is found in a very high proportion of both granulocyte and erythrocyte precursor cells, suggesting a single cell origin[10-13]. This assumption receives strong support from genetic studies. Thus, normal females heterozygous at the *X*-linked glucose-6-phosphate dehydrogenase (G-6-PD) locus have two red cell populations, each expressing the enzyme controlled by a single G-6-PD allele[14-16]; but in heterozygous CML patients whose fibroblasts have both G-6-PD enzymes, the red cells have only a single type, representing one or the other of their two G-6-PD alleles[17]. Moreover, in the red cells of normal subjects heterozygous at the autosomal 6-phosphogluconate dehydrogenase locus, both alleles are expressed; however, in one CML patient heterozygous at this locus, only one of the two alleles was expressed in the red cells, while both were expressed in the fibroblasts[18]. The most likely explanation for this aberration lies in a genetic mechanism such as deletion in a single precursor cell.

Table 1. Xg^a PHENOTYPES IN THE FAMILIES OF ELEVEN FEMALES WITH CML ASSUMED TO BE Xg^a/Xg HETEROZYGOTES ON GENETIC EVIDENCE

				Xg^a Phenotypes

HZ	Present	+	+	0	1	1	0

NT, Not tested.

In testing the blood of CML patients for this purpose, the assumption is made that the red cells in peripheral blood reflect the phenotype of the CML clone and not the small number of "contaminating" normal cells which may be present. The validity of this assumption was shown by making an artificial mixture consisting of varying percentages of Xg(a+) and Xg(a−) red cells from normal male hemizygotes and testing them with the same anti-Xg^a and antiglobulin sera used for testing CML patients. It was found that when the proportion of Xg(a−) to Xg(a+) cells was 5 : 1 or more, no agglutination was visible. Thus, even if the Xg(a+) normal cells "contaminating" a clone of Xg(a−) cells made up as much as 16 per cent of the total, the phenotype would still be read as Xg(a−).

Thirty-seven females with typical CML were studied. Thirty-two were found in Mexico and the remainder in Seattle and Baltimore. No patient had been transfused within two months of testing. The Ph[1] chromosome was demonstrated in the myelogenous cells of twenty-six patients, including the two who were children. Karyotypes could not be undertaken in the remaining cases; however, they had the typical findings and course of CML which is usually accompanied by the Ph[1] chromosome. In thirty families, blood specimens from 107 first degree relatives were also tested. Of these thirty patients, twenty had had cytogenetic studies.

Only two subjects with CML were typed as Xg(a−) (both had the Ph[1] chromosome); family studies in both

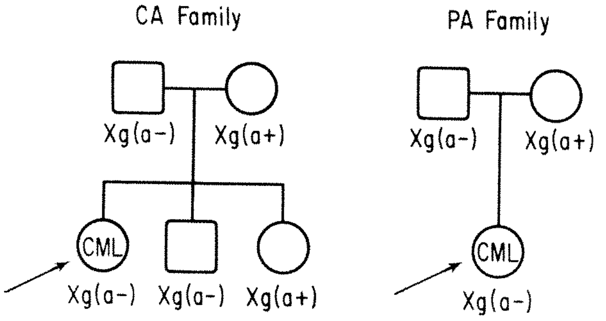

Fig. 1. Pedigrees of two *Xg*(a−) subjects with chronic myelocytic leukaemia.

patients were incompatible with their being *Xg*/*Xg* homozygotes (see Fig. 1). Of the thirty-five females who were typed as Xg(a+), eleven (eight of whom were tested for and found to have the Ph^1 chromosome) were thought to be Xg^a/Xg heterozygotes on the basis of family studies (see Table 1). The results of other genetic marker tests provided no evidence for non-maternity. If random fixed Xg locus inactivation occurs, the probability that all eleven heterozygotes would be Xg(a+) is one in 2,048 (one in 256 if only the eight patients in whom the Ph^1 chromosome was demonstrated are considered).

These findings suggest that the Xg locus does not undergo fixed inactivation in CML red cell stem cells and perhaps not in normal erythrocyte precursor cells either. Nevertheless, alternative possibilities must be considered, such as phenotype alteration due to CML or its therapy, large-scale "contamination" of the CML clone with normal cells, failure of inactivation in abnormal stem cells, non-random inactivation of the *Xg* allele in such stem cells or synthesis of Xg^a antigen in cells other than red cells.

It is unlikely that CML or its therapy changes the Xg phenotype from Xg(a−) to Xg(a+), for two of the Ph^1-positive patients being treated with busulphan were typed as Xg(a−), three of thirteen males with CML were typed as Xg(a−), and no discrepancies in Xg inheritance were encountered in the thirty-nine families studied (thirty families of female and nine of male patients). The possibility of large-scale contamination of the CML clone with normal cells is refuted by the observation that in almost all cases of Ph^1 positive CML more than 85 per cent of the dividing myelogenous cells have the abnormal chromosome[19]. There is no reason to suspect that the initial event leading to CML preferentially occurs in an Xg(a+) stem cell, or that the chromosome carrying the *Xg* gene is non-randomly inactivated. These possibilities, however, cannot be formally excluded. It is conceivable that inactivation at the Xg locus does occur in normal stem cells, but not in the CML progenitor stem cell, or that the locus is reactivated secondary to CML. This would of necessity occur preferentially for the Xg locus, for fixed inactivation at the X-linked G-6-PD locus has been demonstrated in CML cells[17].

From these data we conclude that either the Xg locus does not undergo random fixed inactivation in CML red cells and perhaps in red cells in general, or that the Xg^a antigen is not synthesized in the red cells themselves. Although the latter possibility could explain our observations and those of Gorman *et al.*[6], there is currently no evidence to support a separate site of Xg^a antigen synthesis[7].

We thank the following physicians for their help in securing specimens from patients and their families: Drs R. JiJi, R. Luddy and B. Sigman in Baltimore (University of Maryland School of Medicine), F. Romero in Guadalajara, A. Gomez-Leal and G. Rico in Monterrey, S. Ibarra in Puebla, E. Torre in San Luis Potosi, and E. Facilitation of Metastatic Growth by Antilymphocyte Serum

IN 1967, we described the phenomenon of concomitant immunity evoked by a homotransplantable lymphoma in hamsters[1]. Although growing progressively at the site of transplantation, this tumour initiates a strong and specific immune response such that a second (similar) tumour graft is rejected[2]; the immune response is cell-mediated and is reminiscent of a homograft reaction[3]. A second important manifestation of concomitant immunity in tumour-bearing hamsters is the apparent suppression of metastatic growth[1]: viable tumour cells are demonstrable in the blood and regional lymph nodes[4], but there are intense reactive changes in the lymphoid tissues[3,5,6] and metastatic deposits are not established. It follows that if concomitant immunity were weakened in some way, foci of metastatic growth would be expected to appear. One way is to remove the main immunogenic stimulus by excising the tumour 7 days after grafting[7], a procedure which is followed by the development of metastatic deposits in most animals. We now report results indicating that metastatic growth is also favoured by immunosuppression with antilymphocyte serum (ALS).

First, twenty-four young male golden hamsters (75–90 g) from an inbred line (MHA)[8] were used. Cell suspensions of the homotransplantable lymphoma were prepared[3] and 0·5 ml. of a suspension containing 1×10^7 cells/ml. was injected subcutaneously into the right flank of all animals. They were then divided into three equal groups: eight hamsters were treated with a rabbit anti-hamster thymocyte serum prepared according to the method of Levey and Medawar[9]; eight were treated with normal rabbit serum (NRS); and eight received culture medium 'M 199'. Injections were given intraperitoneally, undiluted, in doses of 0·25 ml. on days 1, 3, 6, 10 and 13 after inoculation of tumour. On day 20, peritoneal exudates were raised in all animals by injecting 3 per cent starch solution[10]; the peritoneal cells were collected on day 22, and the hamsters were then killed. Autopsies revealed, first, that the tumour grafts removed from ALS-treated animals were larger than those from control hamsters (injected either with normal rabbit serum or 'M 199') and showed less variation in weight (Fig. 1). This suggests that tumour growth is more uniform when the immune response is impaired. Second, metastic deposits were found in five out of eight hamsters treated with ALS but in none of the control animals. They occurred in the axillary, mediastinal and perirenal lymph nodes and in the periscapular brown fat; no metastases were seen in the lungs or liver.

Concomitant immunity was tested on peritoneal exudate cells in cell transfer tests[11]. In addition to the three groups of eight tumour-bearing animals, six normal MHA hamsters without tumours were also injected intraperitoneally with 3 per cent starch. Suspensions of peritoneal exudate cells from these thirty animals were prepared, mixed with lymphoma cells in a proportion of 2 : 1, and 6×10^6 cells were injected subcutaneously into eighteen normal isogenic MHA recipients. Peritoneal exudate cells from tumour-bearing hamsters treated with ALS were ineffective in suppressing tumour growth in the recipients (Table 1). By contrast, immunity in tumour-bearing animals injected with normal rabbit serum remained intact and their exudate cells completely suppressed tumour growth in the recipients. Treatment with ALS seems to weaken tumour immunity but does not abolish it.

Table 1. DEPRESSION OF TUMOUR IMMUNITY AFTER TREATMENT WITH ALS DEMONSTRATED BY CELL TRANSFER TESTS

Test source of peritoneal exudate cells	No. of recipients developing tumours
Tumour-bearing hamsters treated with ALS	4/6
Controls	
Tumour-bearing hamsters treated with NRS	0/6
Normal hamsters	6/6

Because the tumour under study is a lymphoma, we investigated whether ALS acts mainly on the tumour or on the immune cells. Peritoneal exudate cells were obtained from eight hamsters, inoculated 14 days previously with 5×10^6 tumour cells, and from six normal hamsters. The cells were incubated for 1 h at room temperature in 1 ml. ALS, 1 ml. NRS or in 1 ml. 'M 199'. The tumour cells were similarly incubated in 1 ml. ALS or 1 ml. 'M 199'. ALS and NRS were always heat-inactivated and diluted 1 : 10 before use. There was no evidence of cytotoxicity according to the trypan blue exclusion test[3]. The cells were then washed three times and mixed (see Table 2). As in the previous experiment, a ratio of exudate cells to lymphoma cells of 2 : 1 was fixed and a total of 6×10^6 cells was injected subcutaneously into normal MHA recipients. The results (Table 2) indicate that ALS does not act directly on the lymphoma cells but on the peritoneal exudate cells whose normal ability to suppress tumour growth in isogenic recipients is impaired after treatment *in vitro* with ALS.

The present results illustrate another way in which ALS may potentiate malignant disease. The action of oncogenic viruses such as SV40, Rauscher leukaemia virus and polyoma is potentiated in mice treated with ALS[12–14]. There is some evidence that ALS may augment the effect of chemical carcinogens[15,16] and it may also favour the growth of allogeneic tumour transplants[17,18]. Our results, together with those of Fisher, Soliman and Fisher[19], make it clear that, in certain circumstances, ALS can facilitate metastatic growth. This seems to be a consequence of immunosuppression rather than any direct action on the lymphoma cells themselves, but the identity of the relevant target cells is uncertain. The noncommittal term "peritoneal exudate cells" has been used deliberately because such exudates always contain 5–10 per cent of small lymphocytes. It has not been established whether ALS acts only against this minority of lymphocytes, or against both lymphocytes and macrophages. Some reports[20,21] suggest that ALS may indeed have anti-macrophage activity, but the evidence is conflicting[22].

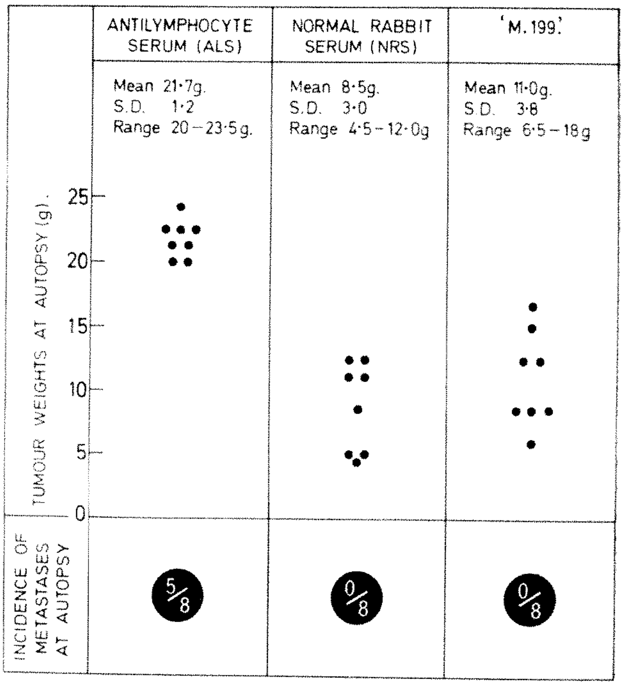

Fig. 1. Tumour weights and incidence of metastases in hamsters treated with ALS, NRS or 'M 199'; 22 days.

Extrapolation of the present results to man would be premature, but there is growing evidence that patients maintained on long-term immunosuppressive treatment may be prone to develop neoplasia[23–25]. Most of the tumours so far reported have been lymphomata; if these lesions show any unusual tendency to disseminate, a relationship in man between prolonged immunosuppression and enhanced metastatic growth may well emerge.

Table 2. CELL TRANSFER TESTS DESIGNED TO DEMONSTRATE SITE OF ACTION OF ALS

Source of peritoneal exudate cells	Tumour cells	No. of recipients developing tumours
(*a*) From tumour-bearing animals		
Treated with ALS	Untreated ('M 199')	5/6*
Treated with NRS	Untreated ('M 199')	0/6
Untreated ('M 199')	Treated with ALS	0/6
(*b*) From normal animals		
Untreated ('M 199')	Untreated ('M 199')	12/12

* Tumours measuring 0·7–1·0 cm in diameter developed at 1 week after inoculation, but they all regressed 1 week later. At this time the immune status of all the recipients listed in this table was tested by transfer tests with peritoneal exudate cells. With a ratio of three exudate cells to one tumour cell, it was found that cells from animals which had previously developed tumours completely inhibited tumour growth in the new recipients ; cells from hamsters which had not developed tumours were without effect. This suggests that the five recipients shown in the first entry on the table were indeed immunized and that their state of immunity was probably responsible for the subsequent tumour regression which was observed. The results also suggest that the inactivation of immune cells brought about by ALS was not, in the present circumstances, complete.

Desensitization to Acetylcholine of Frog Tonic Muscle Fibres

IT is known that depolarization of the postsynaptic membrane of muscle fibres caused by acetylcholine gradually decreases as a result of its prolonged action: after some time the membrane potential may attain its initial level despite the presence of acetylcholine. This decrease in the sensitivity of the postsynaptic membrane —desensitization—has been investigated either in phasic (fast) muscle fibres of the frog or in mammalian muscle fibres[1-3]. Neither type of muscle fibre develops permanent contraction in response to the action of acetylcholine. We report here findings relating to desensitization in tonic (slow) muscle fibres of the frog which are known to be responsible for acetylcholine induced contraction of the whole muscle.

The experiments were performed on single tonic fibres isolated from the ileofibularis muscle of the frog, *Rana temporaria*, during January and February. The tonic fibres were distinguished by their ability to maintain tension at high external potassium concentrations (for details see ref. 4). The isolated fibre was fixed in a chamber specially arranged for microelectrode investigations. Ringer solution (in mM): Na^+, 111; K^+, 2·5; Ca^{2+}, 1·8; Cl^-, 120·6; HCO_3^-, 2·4. Desensitization was evoked and registered by the method of Katz and Thesleff[2]. Both channels of the double-barrelled micropipette were filled with 2 M acetylcholine chloride.

In all the experiments on eleven end-plates (nine isolated tonic fibres) the amplitude of test responses to brief pulses of acetylcholine from one channel of the double-barrelled micropipette slowly decreased when a light conditioning dose of acetylcholine from the other was given (Fig. 1). The rate of decrease was found to depend on the amplitude of the conditioning depolarization: the greater the amplitude, the faster the decrease of test responses. The rate of reduction of the responses induced by various amplitudes of conditioning dose is similar to that described for fibres from the sartorius muscle of the frog[2,5-7]. The rate of recovery of the test response amplitude after switching off the conditioning current was relatively constant and independent of the onset rate of desensitization (Fig. 1), which is also in accordance with the results obtained for the phasic fibres[2].

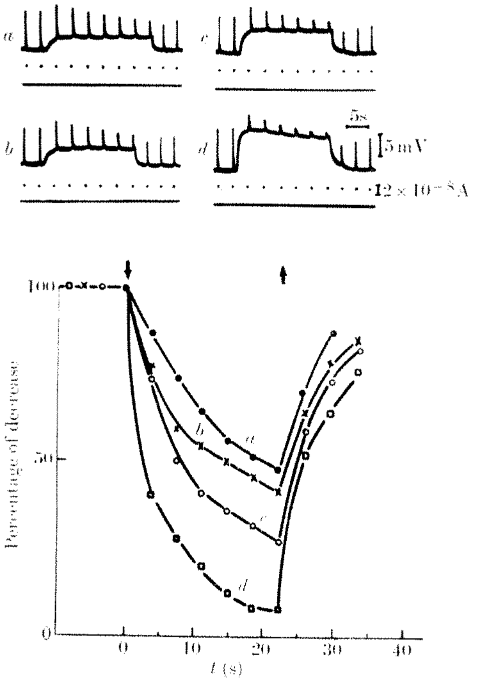

Fig. 1. Desensitization produced by different conditioning doses of acetylcholine at a single end-plate spot of tonic fibre. *Top:* intracellular records of acetylcholine potentials (upper trace). Test pulses and conditioning currents of different strengths were passed through separate channels of a double-barrelled micropipette containing acetylcholine. Lower trace: monitoring of the current through the micropipette containing acetylcholine. *Bottom:* graph showing the rate of onset and recovery of acetylcholine desensitization. The curves were plotted according to corresponding records (*a–d*). Ordinate: relative amplitude of test response; abscissa: time (s). The arrows show the commencement and end of the conditioning current.

To determine the role of desensitization in the mechanism whereby tension is maintained by tonic fibres in the presence of acetylcholine, a simultaneous registration of changes in membrane potential and mechanical tension of these fibres was carried out. Isometric tension was recorded using the mechano-electric transducer 'RCA 5734'. Substitution of the Ringer solution for one containing 2×10^{-5} M acetylcholine caused a decrease in potential of 27–45 mV and a decrease in the tension developed by the fibres. The depolarization amplitude and tension began to fall rapidly even though acetylcholine remained present in the bath (Fig. 2). The same result was obtained with carbocholine (1×10^{-4} M), a cholinomimetic compound not hydrolysed by cholinesterase: a gradual decrease in the effect of acetylcholine is evidently not related to its destruction by cholinesterase.

In control experiments on the same fibres the degree of polarization and tension caused by the elevation of $[K^+]_0$ to 80 mM does not diminish within 1 h. Thus the decrease in tonic fibre contraction induced by acetylcholine is not caused by peculiarities of contraction nor by membrane-myofibrillar coupling mechanisms.

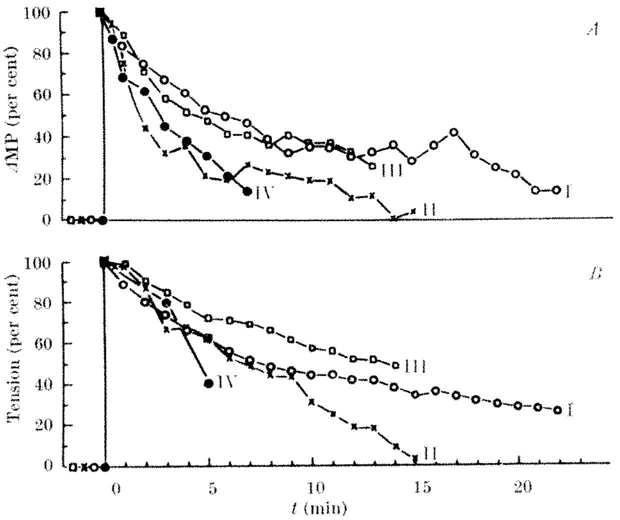

Fig. 2. Simultaneous changes in (*A*) membrane potential (ΔMP) and (*B*) contraction of single tonic fibres in a bathing solution of acetylcholine (2×10^{-5} M). I–IV: individual fibres. The zero on the time axis denotes the onset of the action of acetylcholine.

One cannot overlook the fact that it takes the same time for the membrane potential of tonic fibres and of phasic fibres to return to the initial level in the presence of acetylcholine. Frog tonic fibres are sensitive to acetylcholine only in certain limited zones of their surface corresponding with the points of innervation of these fibres[8]. The areas of these zones are less for tonic than for phasic fibres. Because the rate of desensitization in the former is not less than that in the latter, the ability of tonic fibres to contract under the influence of acetylcholine cannot be assigned to any specific characteristic of their cholinoreceptive zones. These fibres have some synapses located at a distance less than the length constant of their surface membrane[8,9], so that the whole membrane seems to be depolarized electrotonically under the action of acetylcholine. The peculiar character of membrane-myofibrillar coupling helps to maintain contraction for a long period of time[10]. Even so, it lasts only as long as the depolarization of the fibre membrane is maintained: that is, in the case of the acetylcholine effect, up to the onset of desensitization.

Abnormalities in Platelet 5-Hydroxytryptamine Efflux in Patients with Infantile Autism

AMONG the heterogeneous group of children showing autistic symptoms, Kanner described a small sub-group with what he termed "infantile autism"[1]. Rimland[2] suggested that the reticular formation, known to contain 5-hydroxytryptamine (5-HT) (ref. 3), may be involved.

The blood platelet may be used as a partial model for the 5-HT containing neurone[4]: both cells transport 5-HT by an energy dependent process, store it in subcellular organelles of similar electron microscopic appearance and metabolize 5-HT in a similar way[5]. If the platelet model is valid, then the results described here may indicate that 5-HT is involved in a severe psychotic illness.

The subjects were six children aged 4 to 14, diagnosed by Rimland as having infantile autism[6]. No patient had signs of organic brain disease; no drugs were given for one month before experiment. Platelet 5-HT determinations in six autistic and six normal children of comparable age were made in triplicate, as described by two of us[7]; ATP was measured by the technique of Holmsen, Holmsen and Bernhardsen[8]. Platelets were counted with a 'Model B' Coulter counter (Coulter Electronics, Hialeah, Florida), and the cell size determined with the instrument and with thrombocytocrits[9].

In experiments where 5-HT uptake was investigated, platelet rich plasma was incubated with 10^{-5} M ^{14}C–5-HT (specific activity 9·6 mCi/mmole) for 90 min at 37° C in 5 per cent CO_2 : 95 per cent O_2 to load the cells with amine[7]. The degree of 5-HT binding to the platelets was assessed by resuspending the 5-HT loaded cells in fresh plasma from the same subject and reincubating at 37° C for 90 min. At the end of all uptake and efflux experiments, the platelets were separated from plasma by centrifugation, and total radioactivity in platelets and plasma was estimated by liquid scintillation spectrometry. Values refer to the mean ± standard error of the mean.

Table 1. SIZE, NUMBER, 5-HT CONTENT AND UPTAKE CAPACITY OF PLATELETS FROM NORMAL AND AUTISTIC CHILDREN

	Normal	Autistic
Mean platelet size (μm)^3	19·3 ± 1·2	19·8 ± 1·1
Cells/ml. plasma ($\times 10^8$)	3·51 ± 0·22	4·38* ± 0·36
Endogenous 5-HT (nmoles 5-HT/10^{11} platelets)	1,064 ± 94	838 ± 104
Uptake capacity (net uptake of ^{14}C–5-HT; nmoles 5-HT/10^{11} platelets)	1,080 ± 97	1,371 ± 66
ATP μmoles/10^{11} platelets	5·53 ± 0·51	6·65 ± 0·74
ATP : 5-HT	2·58	3·01

* $P < 0·05$.

Values are the mean ± standard error of the mean of six determinations (made in triplicate) with six normal and six autistic children. The ratios ATP : 5-HT are calculated from the values for total 5-HT (endogenous + uptake capacity) given in the table.

The mean platelet size was not changed in autistic subjects (Table 1); but the number of platelets/ml. plasma was significantly increased. There was no concomitant increase in endogenous 5-HT; rather the concentration of amine was slightly diminished. Platelet ATP was also unchanged, and the ATP : 5-HT ratio was normal.

Autistic platelets accumulated 5-HT to a slightly greater extent than normal, 2·6 times the endogenous content, compared with 2·0 times for normal platelets. This was associated with a slight but not significant increase in ATP. More tests would be required to show whether the autistic platelets were saturated, so the ATP : 5-HT ratio must be considered tentative for autistic cells. Our procedure is known to saturate normal platelets with 5-HT (ref. 10).

Although the 5-HT uptake capacity was unchanged or increased in platelets from autistic subjects, their ability to retain the amine was defective. First, normal and autistic cells loaded with ^{14}C–5-HT lost a similar percentage and total amount of radioactivity during the resuspension procedure alone, before reincubation for 90 min (Fig. 1), indicating that the experimental technique did not increase the fragility of autistic platelets more than normal cells. Consequently, the two-fold increase in efflux of radioactivity from autistic platelets (Fig. 1) represents a definite abnormality, but it did not arise from lack of ATP resulting in diminished binding of 5-HT. Because of the limited opportunity to take blood, we do not know whether the efflux of radioactivity represented 5-HT, 5-hydroxyindolylacetic acid or 5-hydroxytryptophol, an important metabolite of platelet 5-HT (ref. 4).

There are few reports of biochemical studies of 5-HT in autistic children and none where an unequivocal diagnosis of primary infantile autism was made[11-14]. The effects described include reduced excretion of 5-hydroxyindolylacetic acid after a tryptophan load[11]; elevated blood 5-HT (ref. 12) and reduced uptake of 5-HT (ref. 14) by platelets.

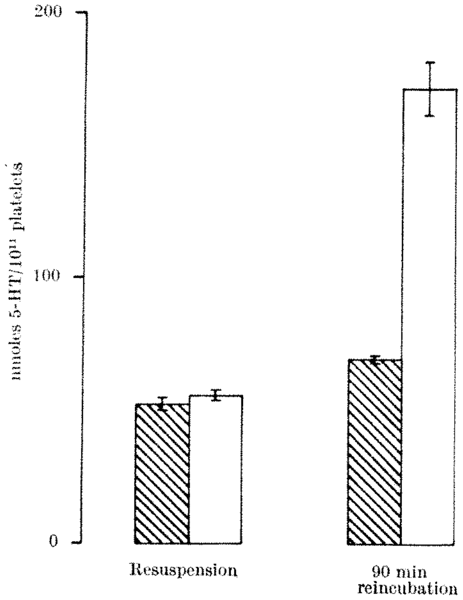

Fig. 1. Efflux of radioactivity. Hatched columns, normal; white columns, autistics.

Because we find a marginal increase in 5-HT uptake and platelet ATP, the increased efflux of 5-HT does not arise from lack of ATP but from some other effect related to 5-HT or its metabolites. In this regard the effects differ from those seen in Down's syndrome where there is also efflux of 5-HT from platelets, which results from defective binding, as there is a lack of ATP (ref. 15).

Thus it must not be assumed that increased efflux of platelet 5-HT is confined to autism; but if the platelet is a valid model for the serotoninergic brain neurone, abnormalities in 5-HT synthesis, binding metabolism and turnover may play a part in autism and other psychotic syndromes.

We thank Dr Bernard Rimland for his assistance in locating and diagnosing the patients in this study. This work was supported in part by grants from the US National Institutes of Health.

Sensitive Quantitative Determination of Chlorpromazine Metabolites

DIMETHYLAMINONAPHTHYL sulphonyl chloride (dansyl chloride) has been used in recent years as an end group analytical reagent in the study of protein structure[1] and in the determination of amino-acids[2-4]. Dansyl chloride reacts with primary and secondary amines and with phenolic hydroxyl groups[4]. Chlorpromazine, after administration to patients, yields over twenty known metabolites[5]. At least ten of these metabolites possess either an amino or a phenolic hydroxyl group, or both, as potential reactive sites for dansyl chloride coupling. We have studied the reactivity of dansyl chloride with the chlorpromazine metabolites listed in Table 1.

To 0·314 μmoles of the metabolite dissolved in 0·1 ml. of acetone in a 'Pyrex' test tube were added 0·1 ml. of 1·48 μM dansyl chloride in acetone and 10 μl. of 0·3 M sodium phosphate–NaOH buffer (pH 12). The tube was stoppered and shaken overnight. Twenty ml. of the reaction mixture was spotted on each of several 100 μm Eastman thin layer chromatography plates (20 cm × 20 cm) and many different solvent systems were studied to obtain the optimum fractionation. Table 2 includes the solvent mixtures appropriate to the separation of various metabolites with their corresponding R_f values. Reaction products were located by the appearance of brilliantly fluorescent spots on thin layer chromatograms which on spraying with the Forrest reagent[6] became purple, confirming the presence of a phenothiazine nucleus in the

spot. The fluorescent colour of the spot as well as its R_f value were clearly different from those of the reactants and the side product(s)—dansyl sulphonamide and dansyl sulphonic acid.

Dansyl metabolite spots were cut out and extracted with spectrofluorometric grade ethanol (prepared by distilling ethanol over solid KOH) with the help of a 'Vortex' shaker. The excitation and fluorescence maxima of the extracts were determined on an 'Aminco Bowman' spectrophotofluorometer, with stabilized xenon lamp as the light source and an X-Y plotter as the recorder. As little as $3{\cdot}14 \times 10^{-10}$–$3{\cdot}14 \times 10^{-9}$ g of the metabolite was quantitated when different dilutions of the dansyl metabolite products were estimated on a Turner 'Model 110' fluorometer fitted with the proper filters and a high sensitivity door.

Further details will be published elsewhere. We are applying this method of quantitation to study the kinetics of appearance of the chlorpromazine metabolites in the body fluids of animals and schizophrenic patients.

We thank Drs E. G. Erdos and H. Y. T. Yang for valuable discussions and the US National Institute of Mental Health for test samples of various chlorpromazine metabolites.

Inhibition of Mauthner Cells by Allylglycine

IN view of the possibility that glycine or glycine-like substances are inhibitory transmitters in the vertebrate central nervous system (CNS)[1,2], it is particularly interesting that the derivative, allylglycine (2-amino-4-pentenoic acid), causes convulsions when injected into mice and rats[3,4]. Last year it was reported that allylglycine *in vitro* and *in vivo* reduced the synthesis of the depressant amino-acid, γ-amino-butyric acid (GABA)[5], which has itself been suggested as a neural inhibitory substance[6,7]; it seemed possible therefore that the convulsant properties of allylglycine may be due to a reduction in the concentration of GABA which it produces within the brain[5]. This communication describes an investigation of allylglycine on the Mauthner cells of goldfish, and in particular any action it may have either directly on these cells or on inhibitory pathways converging on them.

Goldfish (*Carassius auratus*) weighing 80–120 g were kept at 8°–20° C and injected intramuscularly with 10–15 mg of allylglycine (0·5 M in isotonic saline). Usually within 10–24 h the fish developed a characteristic behaviour consisting of erratic, powerful and apparently uncontrolled swimming, interrupted by relatively quiet periods (lasting about 10 min) during which there were forceful respiratory movements of the jaws and gills. This total activity was judged to correspond to the convulsive behaviour which develops in rats about 2 h after similar injections. The interval between the injections and the development of "convulsions" in the fish was reduced to 2–3 h if the fish were maintained at 30° C. Fish in which convulsions had been induced by allylglycine were anaesthetized with MS222 (Sandoz) and prepared for recording. Glass micropipettes filled with potassium chloride and citrate were used to record intracellularly from the Mauthner cells and in some experiments double and triple barrelled micropipettes filled with glycine (2·5 M, *p*H 3), glutamate (2 M, *p*H 7), and allylglycine (1 M, *p*H 4·5) were positioned close to the cells for extracellular iontophoretic injections. Two inhibitory inputs were investigated, the late collateral inhibition (LCI) and the contralateral VIII nerve inhibition[8], both in the "strychnine-sensitive" category[9,10]. The change in conductance of the cell membrane, measured by the decrease in antidromic spike amplitude, was a convenient measure of inhibition[8-11].

The results indicated quite clearly that the duration and extent of both LCI and VIII nerve inhibitions were

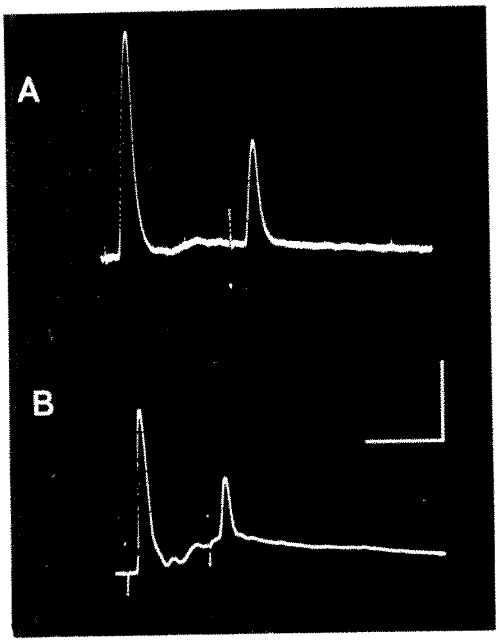

Fig. 1. Physiological inhibition of Mauthner cells in normal fish (*A*) and "convulsant" fish injected with allylglycine (*B*). The traces show the late collateral inhibition (LCI) evoked by a conditioning spike and tested by a second antidromic spike after a delay of a few milliseconds. Inhibitory conductance change is measured by the decreased amplitude of the test spike. The inhibition is similar for both animals. The VIII nerve inhibition (not shown) was also similar for both preparations. The convulsant fish (record *B*) had been injected with 12 mg of allylglycine. Calibrations were 10 mV (vertical) and 4 ms (horizontal).

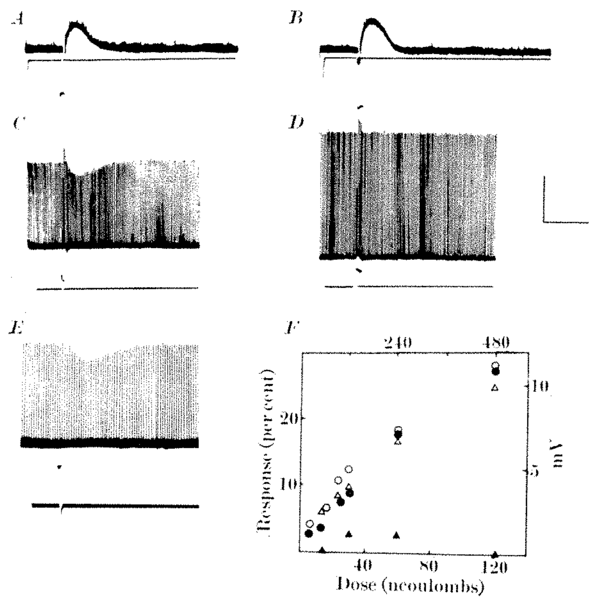

Fig. 2. Effects of iontophoretically applied glutamate, allylglycine, and glycine on the Mauthner cell, before and after injection of strychnine. *A* and *B* show the membrane depolarization (upper trace) caused by a brief pulse of current applied through the glutamate barrel (downwards deflexion in lower trace). *C*, *D* and *E* show records made intracellularly of antidromic spikes (upper trace) and iontophoretic currents applied through the pipette containing the drug (upwards deflexion in lower trace); a decrease in spike amplitude is a measure of the resultant inhibitory conductance change. *C* and *D* are the effects of iontophoretically applied allylglycine, and for comparison, *E* shows the effects of glycine (note different time scale). *A*, *C*, and *E* were taken before, and *B* and *D* after intramuscular injection of 3 mg of strychnine. *F* summarizes the dose response relations of glutamate and allylglycine before and after strychnine had been given; ○, glutamate control; △, allylglycine control; ●, glutamate after strychnine, ▲, allylglycine after strychnine. In *F*, the abscissa is the dose in coulombs $\times 10^{-9}$ (glutamate on top axis, allylglycine on bottom) and the ordinate is the response (mV depolarization for glutamate on the right, percentage reduction of antidromic spike amplitude for allylglycine on the left). Calibrations are: vertical bar, 10 mV and 5×10^{-7} A, and horizontal bar, 4 s for *A*, *B*, *C*, *D* and 2 s for *E*.

normal in convulsant fish (Fig. 1). When iontophoretically ejected on to the cells of normal fish, allylglycine had a direct inhibitory action similar to that of both glycine and GABA, that is, it produced a marked change in conductance with little concomitant change in membrane potential (when recorded with pipettes of potassium citrate). To test whether the actions of allylglycine, like those of glycine itself, are sensitive to strychnine, intramuscular injections of the alkaloid were administered in doses sufficient to block the effects of glycine[10]. Fig. 2 shows, on the left, typical effects of glutamate, allylglycine and glycine before strychnine was injected. Glutamate and allylglycine were applied from a double barrelled iontophoretic pipette near the cell; the typical glycine response from a different Mauthner cell is included to show the similarity of its effects with those of allylglycine. The right side of the figure shows records taken after the injection of 3 mg of strychnine. After strychnine, both glutamate and allylglycine iontophoretic ejection currents were slightly greater, and the spike amplitude increased. The effects of allyglycine were clearly blocked by strychnine. Fig. 2 shows the entire dose-response relations of iontophoretically applied glutamate and allylglycine from a double barrelled pipette before and after injection of strychnine. The concentration of strychnine in the brain was presumably increasing while the records in Fig. 2*F* were being made, which accounted for the complete block of the last response to allylglycine (the largest dose shown in the graph). The lack of any significant alteration in the two glutamate dose-response curves indicates that the results cannot be explained by the movement of the double barrelled pipette containing the drug away from the cell.

It seems therefore that allylglycine can produce "convulsions" in goldfish, but during the convulsive period the collateral and VIII nerve inhibitions are normal. These experiments do not support the interpretation that the convulsions are caused by alterations in inhibitory processes which are sensitive to strychnine. Furthermore, iontophoretically applied allylglycine has a direct inhibitory effect on the membrane which is blocked by strychnine. In view of this, and of the similarity in structure and actions of allylglycine and glycine, it seems that these two substances may be reacting at the same membrane sites.

Fast Presentation Rates and the Recall of Item and Order Information

SEVERAL investigators have suggested recently that there are two stages in short-term memory—a fast decaying buffer store and a more stable and organized store resulting from scanning, rehearsing and encoding operations[1-3]. In this context, rate of presentation should have two effects. Fast rates, for example, minimize the effective decay in the buffer store but at the same time reduce the opportunity for rehearsal. Posner[4] also suggests that increasing rate of presentation will show improved recall only in tasks which minimize the importance of retrieval strategies.

Although data on varying rate are sometimes inconsistent[5], it seems that sufficiently high rates (more than two items/s) produce increasing deterioration in recall[6]. Although these results seem to contradict the evidence for transient buffer storage, the latter has involved neither sequential inputs nor ordered recall.

We have attempted to clarify these issues by a theoretical and experimental distinction between order information, in which an item's serial position is stored, and item information. We suggest that the rehearsal possible at slow rates is largely used to organize order information, and that loss of order information leads to a deterioration in performance at high rates, when the traditional ordered recall is used.

Sequences of eight digits were prepared on 16 mm black-and-white movie film. Digits were drawn from random number tables, with two constraints: no two successive digits could be the same, and runs of digits in their correct numerical sequence were excluded. Each digit in a sequence occupied one frame of film only. By varying the number of blank frames between successive digits, the rates of presentation at a film speed of 24 frames/s were 12, 8, 6, 4, 2, $\frac{1}{2}$ and $\frac{1}{4}$ digits per second. Five different sequences of digits were prepared for each presentation rate, and were block randomized. Subjects were given all thirty-five sequences, followed by a short rest before repeating the same sequences a second time (there was no evidence to suggest learning of sequences).

Subjects performed two tasks. In the first, we required serial recall after each digit sequence, with subjects indicating omissions by blanks, and in the second, each sequence was followed by the auditory presentation of two probe digits. Subjects were asked whether each digit had occurred in the sequence. The four possible response alternatives, "yes, yes", "yes, no", "no, yes", "no, no", were arranged to be equiprobable and subjects were informed of this. The serial position of the probe digits was balanced for each rate. In this task the slowest rate was not used. Ten subjects, all university students, performed the two tasks in counterbalanced order.

In the serial recall task, responses were scored both for correct serial position and for item information. One mark was given for each digit recalled in its correct position. Item information was scored by giving one mark for every digit recalled correctly, irrespective of serial position. This gave a maximum possible score of 80 for each presentation rate for both methods. Scores for the ten subjects have been averaged and are shown in Fig. 1 together with standard deviations. Results of the probe digit task are also shown. In this case, we gave one mark for each correct response to a single digit. The maximum possible score was 20 for each presentation rate; again scores for all subjects have been averaged and converted to a percentage correct score for direct comparison on the same axes as the serial recall task. Only the slopes and not the absolute magnitude of the functions can be compared, because the performance measures are differently scaled.

The data for serial recall show that the amount of information recalled decays rapidly at presentation rates above ½ per second; this decay seems to be linear with respect to rate. The standard deviations indicate that variability is fairly constant, and does not seem to depend on rate or on the task. The data show clearly that subjects are able to retrieve digits more successfully than they are able to locate them in their correct serial position for all rates. Even at the fast rate, subjects are able to extract about four digits from the eight-digit sequence, but are only able to locate approximately one or two of these digits in their correct serial position.

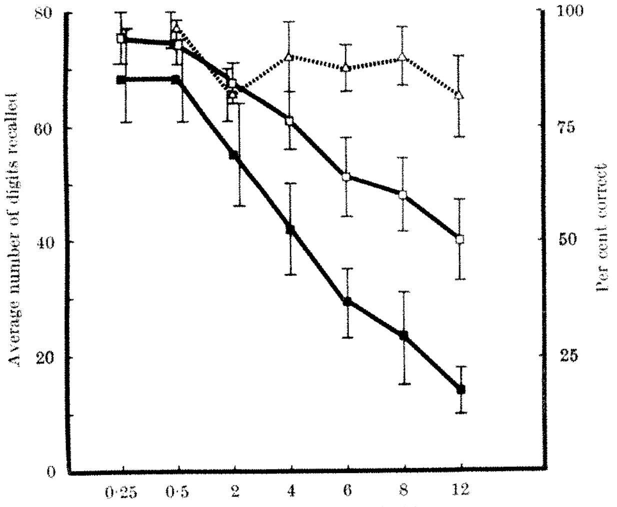

Fig. 1. Recall as a function of rate of presentation; probe recognition (△ - - - △), serial order recall (■—■) and serial order recall scored for items correct (□—□). Data points are means for ten subjects. Variability is indicated by a plot of one standard deviation. Where standard deviations overlap, those for the probe conditions have been displaced to the left and those for serial order recall displaced to the right for the purpose of clarity.

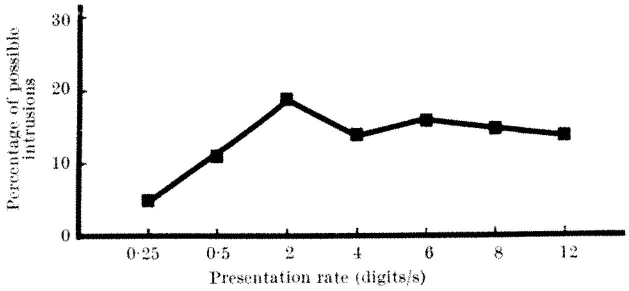

Fig. 2. Number of incorrect inclusions expressed as a percentage of total possible inclusions at each rate for the serial order recall condition.

This finding is further supported by data from the probe digit task. Ability to identify whether or not a digit was contained in a sequence does not seem to decrease systematically as presentation rate increases. At the fastest rate, subjects find no difficulty, and are able to give correct replies to 80 per cent of the probes. Errors to the probe given first (67) and given second (78) did not differ significantly (chi square = 0·84). The main feature of the functions is therefore their divergence with increasing rate. This divergence is evident both for the separation between the means and the standard deviations.

Because the serial recall task lends itself well to a guessing strategy, the component of chance must be isolated. The constraints placed on the randomization of the material make the calculation of a meaningful correction factor extremely difficult. Instead, we have taken, as a measure of guessing, the number of times a subject included in his response digits that were not present in the original sequence. The number of such intrusions made is shown in Fig. 2, expressed as a percentage of the total intrusions that were possible at each rate. Recall performance at the two slowest rates is about 90 per cent, which gives little opportunity to make intrusions. At the fast rates, the number of intrusions decreases slightly with speed of presentation, and the percentages are very low. Furthermore, we found that the number of omissions increases linearly with rate. This evidence seems to suggest that chance guessing is not a significant factor in the differential recall performance found at various rates.

The data for the probe task do not show any systematic deterioration of storage with rate, but suggest a more complex relationship between performance and rates. This is not reflected in the data for the serial recall task scored for content, because the task imposes retrieval constraints[4]. The serial recall data show that the retrieval of order information does depend on slow presentation and consequently on organizing effects of rehearsal. This is consistent with the evidence[7] that grouping preserves order and flattens the classical serial position *U*-curve and also with Neisser's argument[8] that rhythm is the natural carrier for serial order information. More generally, Henderson and Matthews[9] have suggested that rehearsal acts as an addressing system which plays an increasingly important part as retrieval constraints are increased, but which does not affect storage capacity. In this context, it is assumed that probe recognition involves minimal retrieval demands, while serial order recall involves maximal demands, and that serial recall of item information, or free recall, is located in between.

In the probe task, failure to find the improved storage which the buffer store hypothesis strictly requires can be accounted for in several ways. Delay in administering the probe digits adds a constant to retention time, which may mask the effect of increased rate; the fastest rates approach the limits of perceptual resolution and may lead to pre-mnemonic loss of input; and, finally, the diminishing effects of rehearsal with increased rate might be expected to obscure the concomitant increased utilization of buffer storage. These parameters are currently being investigated.

This work was supported by the Defence Research Board of Canada, and was carried out at the Defence Research Establishment, Toronto.

Homoeologous Meiotic Chromosome Pairing in *Triticum aestivum* in which Chromosome 5B is replaced by an Alien Homoeologue

IN the hexaploid bread wheat (*Triticum aestivum* $2n = 6x = 42$) meiotic pairing is confined to fully homologous chromosome partners and inheritance is disomic. This arises from the activity of a single locus (*Ph*, *pairing homoeologous*) distally located on the long arm of chromosome *5B*[1,2]. In the absence of chromosome *5B*, pairing and recombination take place between homoeologous chromosomes, which are genetically related members of the three component genomes, as well as between homologues[3]. Knowledge of the *5B* system is of fundamental and practical significance. It throws light on the process of chromosome pairing during meiosis[4], and assists in the interpretation of the cytogenetic behaviour of polyploid wheat, and indeed of all allopolyploids. Moreover, interference with its activity has been exploited to cause abnormal recombination between homoeologues in order to introduce into wheat chromosomes useful genes from chromosomes of related species[5]. Consequently to extend the understanding of the system, as well as to facilitate its use in breeding work, attempts are continually being made to isolate new wheat genotypes displaying homoeologous pairing.

For this purpose we have been attempting to isolate wheat lines in which the *5B* pair is replaced by a pair of homoeologous chromosomes from a related species that does not have the genetic capacity to prevent the synapsis of homoeologues. The substitution of wheat chromosomes by alien homoeologues in this way involves a simple breeding procedure using as parents 41-chromosome wheat monosomics and 44-chromosome alien addition lines in which a single pair of alien chromosomes is added to the full wheat complement. When the monosomic chromosome in one parent and the alien chromosome in the other parent are genetically related homoeologues, plants can be isolated among derivatives of the breeding programme that are nullisomic for the wheat chromosome originally monosomic but still disomic for the alien chromosome. Such substitution lines often have phenotypes close to those of the original wheat parent[6].

In our attempts to replace chromosome *5B* by an alien homoeologue we used a chromosome of the diploid species *Aegilops umbellulata* ($2n = 14$). Because there is homoeologous pairing at meiosis in 27-chromosome *T. aestivum* × *Ae. umbellulata* hybrids deficient for chromosome *5B*, *Ae. umbellulata* does not carry out a genetic activity that prevents such pairing. Consequently the replacement of *5B* by its homoeologue from *Ae. umbellulata* would be expected to yield a genotype in which there is homoeologous pairing.

The separate disomic addition, to *T. aestivum* 'Chinese Spring', of six of the seven chromosomes of *Ae. umbellulata* was made at this Institute by Kimber[8], and we have subsequently added the seventh. The problem of recognizing the alien chromosome that relates to, and is homoeologous with, a particular homoeologous group of wheat chromosomes is simplified by the comparison of the phenotype of the alien addition line in which it is carried with those of tetrasomic plants of *T. aestivum*. The expectation is of similar phenotypic deviations from the euploid following increased dosage of any homoeologous group whether by tetrasomy or by alien disomic addition. On this principle, using the characters height, ear morphology, hairiness and susceptibility to powdery mildew, the chromosome of *Ae. umbellulata* designated *C* seemed likely to belong to homoeologous group 5. This likelihood was further increased by its morphological resemblance to the chromosomes of group 5. Like them, chromosome *C* has a submedian centromere (Fig. 1*b*). It also has a secondary constriction, delimiting a small satellite, as does chromosome *5D* in its original diploid source, although not in *T. aestivum* (Fig. 1*a*).

To substitute *Ae. umbellulata* chromosome *C* for *5B*, crosses were made between *T. aestivum* 'Chinese Spring' monosomic *5B* and the addition line with chromosome *C* added disomically to 'Chinese Spring'. Hybrids simultaneously monosomic for *5B* and *C* were isolated and self-pollinated and the resulting progeny were grown. In these progeny, the chromosome constitutions of fifty-six plants were checked, and of these three were substitutions with forty-two chromosomes and chromosome *C* disomic. Because of its distinctive small satellites chromosome *C* could be unequivocally distinguished, in somatic divisions, from all members of the wheat complement (Fig. 1*a*)

These disomic substitution plants and their sibs were grown in a glasshouse in continuous light and at a temperature of about 20° C, and their meiotic behaviour was examined at first metaphase. The substitution plants approximated to normal morphology and vigour, and indeed proved to be self-fertile, so that the allocation of chromosome *C* to group 5 was confirmed. The genome of *Ae. umbellulata* is designated C^u and so chromosome *C* will be referred to subsequently as $5C^u$ and the substitution line will be designated $5C^u/5B$ subst.

The other genotypes with which $5C^u/5B$ subst. was compared meiotically were all derived from 'Chinese Spring' and had the following chromosome constitutions. (1) Forty-three or forty-four chromosomes with monosomic or disomic additions of $5C^u$ to the full wheat complement ($5C^u$-mono-addn. and $5C^u$-diso-addn.) (2) Forty-two chromosomes with the normal wheat complement but *5B* and $5C^u$ both monosomic (*5B*-mono/$5C^u$-mono). (3) Forty-two chromosomes and the undisturbed wheat complement (euploid).

All the $5C^u/5B$ subst. plants had multivalents at meiosis and in the plant scored for Table 1 there was a mean of 0·76 multivalents per cell (Fig. 1*c*). Trivalents were more frequent than quadrivalents and there were also associations of five and six chromosomes. Chiasma frequency was low, relative to euploid, and this was reflected in the presence of univalents unrelated to the occurrence of odd numbered multivalents. This pattern of meiotic pairing is closely similar to that of plants of *T. aestivum* nullisomic for chromosome *5B* in which homoeologous pairing is known to occur[3,9]. Because there were multivalents resulting from homoeologous pairing, it can be assumed that some bivalents also formed between homoeo-

Table 1. MEAN CHROMOSOME PAIRING AT FIRST METAPHASE OF MEIOSIS IN *T. aestivum* WITH CHROMOSOME $5C^u$ SUBSTITUTED FOR $5B$ AND IN RELATED PLANTS

Genotype	Chromosome No.	Dosage $5C^u$	Dosage $5B$	Univalents	Mean pairing Bivalents	Mean pairing Trivalents	Mean pairing Quadrivalents	Mean chiasmata per potential bivalent*
$5C^u/5B$ subst.	42	2	0	1·57 (0–7)	18·83 (15–21)	0·40 (0–3)	0·30† (0–1)	1·82 ± 0·23
$5C^u$-mono-addn.	43	1	2	1·73 (1–5)	20·67 (19–21)	—	—	2·15 ± 0·11
$5C^u$-diso-addn.	44	2	2	0·07 (0–4)	21·97 (21–22)	—	—	2·27 ± 0·12
$5B$-mono/$5C^u$-mono	42	1	1	2·00 (2)	20·00 (20)	—	—	2·13 ± 0·15
Euploid	42	0	2	0·00 (0)	21·00 (21)	—	—	2·19 ± 0·11

Figures are for thirty cells per plant, with ranges given in parentheses.
* Potential bivalents; $5B$-mono/$5C^u$-mono = 20; $5C^u$-diso-addn. = 22; remaining genotypes = 21.
† 0·02 quinquevalents; 0·05 sexivalents.

logues. It can be concluded that, in the $5C^u/5B$ subst. condition, the effects of the deficiency of $5B$ are fully expressed and the presence of $5C^u$ does not compensate for the deficiency. On this evidence $5C^u$ is of null effect.

Reduced chiasma frequencies in association with homoeologous pairing, as in the present $5C^u/5B$ subst. plants, have been observed in other $5B$-deficient genotypes and ascribed to synaptic competition between homologues and homoeologues[10]. This competition reduces homologous pairing without guaranteeing homoeologous pairing.

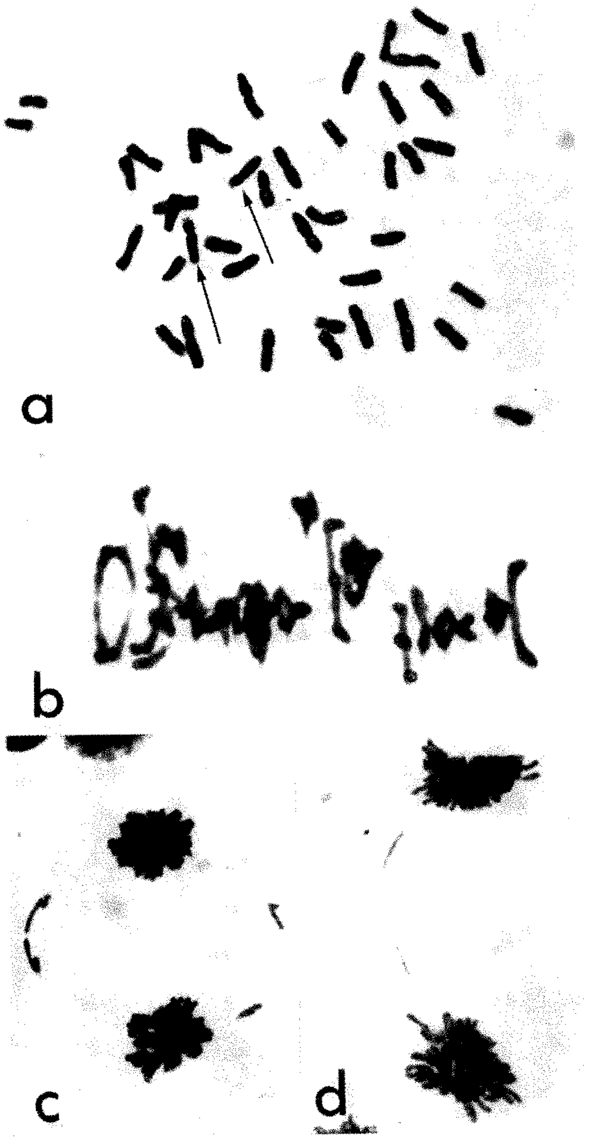

Fig. 1. *a*, Somatic chromosomes in a root tip squash, after pretreatment with *α* bromonaphthalene, of $5C^u/5B$ subst. with forty-two chromosomes and chromosome $5C^u$ (arrowed), with small satellites, disomic. *b*, First metaphase of meiosis in $5C^u/5B$ subst. with nineteen bivalents, and one quadrivalent on extreme left. *c*, First anaphase of meiosis in $5B$-mono/$5C^u$ mono with the monosomic chromosomes laggards and separating into chromatids, $5B$ on the left and $5C^u$ on the right. *d*, First anaphase of meiosis in $5C^u/5B$ subst. with an inversion bridge and fragment.

A further distinctive attribute of meiosis in the $5C^u/5B$ subst. plants was the presence of heterozygosity for a paracentric inversion, revealed by the occurrence of a dicentric bridge and acentric fragment in some first anaphases (Fig. 1*d*). There was no evidence of inversion heterozygosity in the sibs with only homologous pairing, and so it seems likely that the inversion differentiates homoeologous chromosomes and is thus apparent only when they synapse.

The $5C^u/5B$ substitution plants are vigorous, though short and with narrow leaves and stems, and lax spikes, compared with euploids. Furthermore, they are seed fertile and so are manageable as parents in breeding programmes. A progeny of twenty-three individuals derived from selfing a $5C^u/5B$ subst. parent was checked for chromosome constitutions, and twelve plants had forty-two chromosomes and were disomic $5C^u$, so retaining the parental constitution. The remainder had between forty and forty-three chromosomes, and all except two were disomic for $5C^u$. Consequently the $5C^u/5B$ subst. genotype is sufficiently stable for use in experimental and practical breeding work. Its value in the exploitation of homoeologous recombination in wheat breeding may be in providing a pollen-fertile $5B$-deficient condition without the complication of compensating aneuploidy for chromosome $5A$ or $5D$.

Sunlight-induced Killing in *Saccharomyces cerevisiae*

ALTHOUGH ordinary sunlight has long been recognized as potentially deleterious to living organisms, little is known about the nature of genetic damage produced by sunlight or whether there are cellular mechanisms for removing the damage. The existence of cellular recovery systems (repair) has been demonstrated in a variety of organisms for the case of damage due to far ultraviolet light (< 2900 Å; designated here as UV), which is not, however, part of the sunlight spectrum at the Earth's surface (> 2900 Å)[1]. I have used two types of UV sensitive mutants of the yeast *Saccharomyces cerevisiae* to investigate (1) whether the mechanisms available for the repair of UV damage can also act on sunlight-induced lesions, (2) the extent to which sunlight exposure is potentially lethal, and (3) the nature of the lesions involved.

In what follows I use *uvs 9–3* to indicate the third identified mutant allele of the *uvs 9* locus, and *phr 1* for

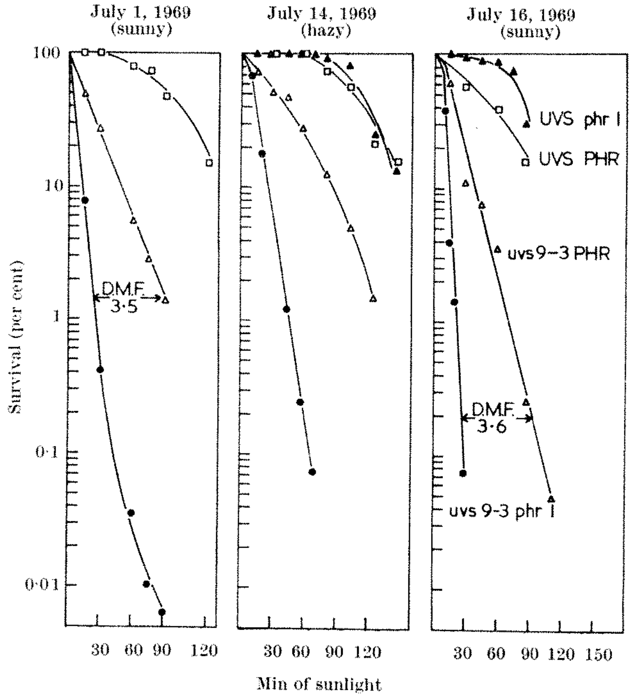

Fig. 1. The response to sunlight of wild type and radiation-sensitive strains of *Saccharomyces cerevisiae*: mutants at the *uvs 9* locus are sensitive to far UV and *phr 1* mutants are unable to photoreactivate damage induced by far UV. Experiments were performed in Mill Hill, London, at temperatures of 32°–34° C.

the first identified mutant allele of the *phr 1* locus. Capital letters signify the wild type. *uvs 9–3* mutants are considered[2] to be defective in excision-repair, a stepwise process of removal and replacement of damaged DNA[3–5], and *phr 1* mutants are incapable of photoreactivation[6], a process in which photoreactivating enzyme attaches to UV-induced pyrimidine dimers and splits them in the presence of visible light.

The UV and photoreactivation responses of the *uvs 9–3 phr 1*, *uvs 9–3 PHR*, *UVS phr 1* and *UVS PHR* strains used in this study have been described, as have been the methods of culturing cells and measuring survival[6]. Differences in survival between two conditions of irradiation or between strains are described by the dose modifying factor (DMF) which is the factor of increase in dose required to equate survival. Stationary phase cells were centrifuged, washed and plated after appropriate dilution to 1 per cent yeast extract, 2 per cent Bacto-peptone, 2 per cent dextrose and 2 per cent agar. Except for the controls, which were placed in aluminium foil, the Petri dishes were exposed to sunlight with lids removed. Experiments were performed on three different days beginning at approximately noon; two were sunny and one was hazy. The total sunlight exposure has been corrected for changes in the dose rate by measuring survival of the *uvs 9–3 phr 1* strain at succeeding 15 min intervals and comparing this survival with that in the first 15 min. Temperatures ranged from 32°–34° C.

The effects of sunlight can be very profound in the absence of genetic repair, as shown in Fig. 1. On a sunny day survival of the *uvs 9–3 phr 1* strain is less than 1 per cent after only 30 min exposure while in the *UVS* strains it is approximately 100 per cent. A major category of lesions seems to be pyrimidine dimers, as shown by the better survival (DMF: 3·5–3·6) of the *uvs 9–3 PHR* strain (which contains photoreactivating enzyme) than of the *uvs 9–3 phr 1* strain (which does not). As for the case of UV-induced killing, photoreactivation of sunlight-induced damage is not 100 per cent effective, so that lesions other than dimers may be involved. The presence or absence of photoreactivating enzyme in the *UVS* strains does not increase survival; this is rather surprising, for after UV treatment of a *UVS* strain the damage is photoreactivable at all levels of lethality. It would thus seem that the dark repair mechanism leaves no damage to be photoreactivated, perhaps because of a relatively slow exposure rate which allows more time for dark repair of pyrimidine dimers. The ability to photoreactivate pyrimidine dimers could be relevant, therefore, in conditions of growth (that is, log phase) which do not leave enough time for dark repair. Although dark repair seems to be nearly 100 per cent effective against lesions that arise during short exposures to sunlight, killing does occur at higher doses. Following 30–60 min of sunlight, significant lethality is detected, and after 2 h nearly 80 per cent of the cells are dead.

The observation that survival characteristics for all the strains are similar on both sunny and hazy days suggests that there is little attenuation of the component of sunlight that can cause killing. The DMF for a hazy against a sunny day is approximately 2, as determined from the survival of the *uvs 9–3 phr 1* strain on the two types of days.

Short exposures to sunlight thus seem potentially very lethal for yeast cells. Harm has reported similar results for bacteriophage and bacteria[7] and has suggested that UV-sensitive bacteria be used as biological dosimeters for sunlight[8]. Because death in yeast can be considerably decreased by photoreactivation and by what is assumed to be excision-repair[6], both of which are known to act on damaged DNA, I conclude that sunlight-induced lesions occurring at low doses are present primarily in DNA. The effect on the *UVS* strains at high doses may result from (1) a saturation of the repair processes—unlikely because the exposure rate is so low, (2) an accumulation of non-repairable DNA damage, or (3) the production of non-DNA lesions, as indicated by the significant killing observed[9] in bacteria at wavelengths greater than 3100 Å. If (2) or (3) is true, the damage can only be expressed when it has accumulated to a particular level because little or no killing is observed at low doses.

The role of repair mechanisms in removing sunlight-induced lethal damage has important human implications. Cleaver[10] has presented evidence suggesting that dark repair occurs in normal human cell lines but is absent in cells from patients having xeroderma pigmentosum, a genetic disease characterized by susceptibility to skin cancer after short exposures to sunlight. Results in the present experiments indicate that xeroderma pigmentosum symptoms may be caused by an extensive amount of sunlight-induced lesions in dermal cells which, in normal cells, would be removed by dark repair processes.

I appreciate the excellent technical assistance of Mr Michael Kairis and the helpful criticisms of Dr Robin Holliday. This work was supported by a US Public Health Service postdoctoral fellowship from the US National Cancer Institute.

Book Reviews

SOCIAL SCIENCE

Behavioral Sociology

The Experimental Analysis of Social Process. By Robert L. Burgess and Don Bushell, jun. Pp. xiii + 418. (Columbia University Press: New York and London, February 1970.) $12.50; 113*s*.

FROM time to time impatience with the "non-scientific" qualitative nature of social science inspires an attempt to develop a rigorous quantified experimental "behavioural" science with its roots in experimental psychology or even physiology. The most notorious of these is the attempt by the Pavlovians to explain all behaviour as a chain of conditioned reflexes. The crude behaviourism of the 1920s and '30s followed this trend, and its excesses were partly responsible for the counter-revolution of the gestalt psychologists and their more modern successors in the field of social psychology. It is the misfortune of such attempts to lead to scientism rather than science and to the reductionism of what Viktor Frankl has described as the "terrible generalisateur (who) turns biology into biologism, sociology into sociologism, and psychology into psychologism"[1].

At first sight this book looks like yet another assault on the sociological citadel in the name of a new behaviourism. But a robust assertion by Homans sets a more reasonable aim:

> "Let us not worry about whether these are sciences at all. Any activity that tries to state relationships between properties of nature, whether or not the statements are exact or general, whether or not they make predictions possible, so long as the test of the truth of the statement lies in the data themselves, is a scientific activity, and by this standard much of the activity of all the social sciences is certainly scientific" (page 1, prologue).

He claims that the ultimate importance of the propositions of behavioural psychology is that they stand as the most general propositions of social science. They do not involve reducing all explanation of behaviour to the behaviour of the isolated individual, still less to concern with individual differences where the interest is in statistical regularities in the behaviour of large groups or classes of individuals. Although he claims his stand is "reductionism", the position he, and the other authors, adopt is not dissimilar to that of Gluckman and Devons[2] to whom reductionism is anathema:

> ". . . some psychologists criticize economics because of its simple and crude assumptions about human motivation; and some psychologists criticize social anthropology because it neglects the complexity of the structure of the personality. But the economist or anthropologist may be making these neglectful assumptions knowingly and deliberately. We argue that the issue is not whether the assumptions are crude, but rather whether they materially affect the analysis and conclusions of economist and anthropologist".

The behaviourism on which the authors draw is the kind familiar in what is now described as behaviour-therapy and derives from the work, largely associated with the name of B. F. Skinner, on "operant" conditioning. This is one of those terms which look more precise than they are. For example, on page 27, operant behaviour is defined as "the behavior of individuals that operates on the environment in such a way as to produce some consequence or change in it which, in turn, modifies subsequent performances of that behavior".

The order of the chapters in the book is designed to alternate theoretical analysis with experimental data. As the latter are by different hands at different times, the strain on the editing proves too great. Thus, for example, the story of the "shaping" of the social behaviour of 13 year old Justin is mentioned in two successive chapters (on p. 281 and p. 304) without any cross-reference. The experimental chapters consist of two kinds of demonstrations: first, that social aspects of behaviour can be "shaped" by means of "schedules of reinforcement", often without the knowledge of the subject(s) that this was being done; and second, that undesirable behaviour of a pathological or criminal nature can be eliminated or greatly reduced by carefully controlled operant conditioning. Perhaps the most advanced of these examples is that which demonstrates how a subject can learn to imitate the general behaviour of a model, not just the specific imitating behaviour that is being reinforced.

Many of these experimental data will prove surprising to nobody and familiar to those who have read Eysenck. That children treated firmly and rewarded for doing what is required, and punished by being removed from the scene and ignored for doing what is to be discouraged, will learn to behave better sounds pretty obvious; what is truly revealing is the realization that our usual methods of treating bad behaviour sometimes reinforce just the reverse of what we intend.

The most important chapter is that by Burgess and Bushell on "Behavioral View of Some Sociological Concepts". Their starting point (p. 274) is given thus:

> "The experimental psychologists who have developed the principles of behavior did so in a highly controlled environment. Within this setting they confined their observations to simple arbitrary responses which were chosen for reasons of experimental ease rather than social significance. Only recently have attempts been made to investigate systematically the application of these principles to the analysis of social behavior".

They then discuss a number of critical sociological concepts. Their discussion of socialization is particularly valuable and, pointing to the important role of the primary group, they observe, "The shaping requirement for intense one-to-one interaction is met more effectively by the primary group arrangement than by any other frequently encountered social device". Acquisition of values by socialization "combines the principles of shaping, the development of conditioned reinforcers, and the graduation from high-density reinforcement schedules to highly intermittent ones". With a surprising degree of success they apply the same approach to role behaviour, verbal behaviour, the concept of the "self", and to the acceptance of behaviour models.

This approach proves less convincing in the chapter by Kunkel on "Behavioral Aspects of Social Change and Economic Development" and in Richard Emerson's chapter on "Operant Psychology and Exchange Theory". Nevertheless, these offer some interesting applications. But Emerson must have the last word:

> "In branching out from operant psychology, this theory has been highly selective and, in large part, arbitrarily so. For example, negative reinforcement (and "aversive control" in exchange relations) has been virtually ignored, despite its obvious importance in social affairs. There is much more available in operant psychology to be drawn upon. But, even more to the point, *this theory* (so far) *has been narrowly selective in choosing operant psychology as its sole psychological base.* Not all psychological knowledge is contained within the operant framework, and the strategy put forth here is free to draw upon reliable and relevant principles wherever they can be found" (p. 404).

What we have then is not a replacement of sociology with a new outgrowth of operant behaviourism, but a solid approach to the underpinning of sociology with a widely based experimental psychology. A. B. CHERNS

ARCHAEOLOGY OF THE FUTURE?

Science in Archaeology

A Survey of Progress and Research. Revised and enlarged edition. Edited by Don Brothwell and Eric Higgs. Pp. 720+40 plates. (Thames and Hudson: London, February 1970.) 147*s* boards; 42*s* paper.

THE publication of a second edition of *Science in Archaeology* only six years after the first edition emphasizes two things: the enormous steps that have been taken in recent years in applying a much wider range of scientific techniques and approaches to the needs of archaeology (720 pages compared with 595) and a slight, but noticeable, change of emphasis. Thus the differences between the two editions are significant because they point to the direction along which the subject is at present developing. Physical methods of dating and prospecting, after a rapid development in the 1950s and early 1960s, now seem temporarily to have reached a slower rate of progress. More has been added on the potassium–argon method and a potentially useful new approach using a fission track technique is summarized, but there the matter rests. Similarly in the fields of microscopy, radiography and the general physical characterization of artefacts, little has been added, apart from a survey of recent work on obsidian and two very useful articles on the use of the scanning electron microscope and the application of X-rays.

One of the most impressive growth points in the subject in recent years has been in the field of statistics and computerization. Innumerable articles have been written attempting, with varying degrees of success, to apply statistical techniques to sometimes rather intransigent archaeological data. The more thoughtful writers have usually preached optimistic caution; the less thoughtful critics have heaped condemnation. Now for the first time we are offered a balanced 44-page consideration of the whole field, written, significantly perhaps, by four authors from the viewpoints of archaeology, anthropology and zoology. The range of approach is wide and sometimes necessarily superficial, but the text is well supplied with pertinent archaeological examples. As an introduction to the present state of knowledge for less mathematically minded archaeologists, this is essential reading.

The second area of rapid development is in the biological application to (or, more strictly, of) archaeology. Mollusca of various kinds are now considered in some detail and there is a very welcome discussion of the problems posed by early animal husbandry. Surprisingly, however, the process involved in the early "domestication" of plants tends to be sketchily treated, and this at a time when so much new work is under way. Valuable though these twenty-three contributions on plants and animals are individually, and many of them are exceptionally good, the overall impression they give is of a fragmentation in approach and interest, when, as the editors point out in their stimulating introductory chapter, the present emphasis should be on the very close integration of archaeology and the biological sciences. The one article to get close to this ideal is a thought-provoking treatment of social organization as a population regulator.

On style and presentation the book is difficult to fault, and the editors have managed to overcome most of the difficulties inherent in producing a compilation of sixty-one contributions. One omission, however, which should be put right in later editions, is the absence of the dating of the individual articles. At a time of such rapid advance it is essential to know when the latest revision of each was carried out.

This is, without doubt, an important work which must be read by all archaeologists and all interested in the archaeology of today and the future. Scientific approaches and techniques are now a part of the substance of the discipline, and only by accepting and building on this premise can there be progress. The diehards of the old school must now sound their final retreat.

Finally the price: seven guineas is a fair price for the hardback, and the publishers will be blessed by generations of students for producing a paperback version for as little as 42 shillings. BARRY CUNLIFFE

PREHISTORIC MEDICINE

Palaeopathology

Diseases and Injuries of Prehistoric Man. By Paul A. Janssens. Pp. xiii + 170 + 75 plates. (John Baker: London, February 1970.) 55*s*.

THE subtitle of this book is a misnomer; almost as much attention is devoted to the diseases and injuries of fossil animals as to those of man. The work is divided into twenty-seven chapters varying greatly in length, content and importance, and bearing titles which in many cases have little connexion with the matter discussed in them.

The author first attempts to define medicine as any action carried out to safeguard man against disease, and finds in it what he terms a science-factor and a law-factor, the latter necessary not only to protect the sick individual but also to protect knowledge. A brief discussion of climate, economy and environment follows. After some consideration of the limitations imposed upon the palaeopathologist by the nature of the material at his disposal he provides a useful but too brief summary of the effects of cremation upon bone. His study of traumata affords him an opportunity to speculate upon the social relationships of early man. A long chapter on palaeolithic art seems to have been included chiefly to prove that prehistoric man had some knowledge of animal anatomy—a not improbable assumption. The discussion of the strange symbols often found on the walls of caves in association with pictures of animals is stimulating and suggestive. From a review of some modern folklore the author derives hypotheses concerning the reason for the frequency with which fractured calvaria are found at ancient burial sites. A short section on anomalies of development and their representation in Egyptian paintings is followed by a more extended consideration of Venus figurines which for the most part exhibit steatopygia. He holds that an important factor in their interpretation is the average duration of life at the time and goes on to present some evidence concerning this average, but omits to demonstrate any connexion between this and the figurines in any explicit way. A reasonably comprehensive account of the occurrence of tumours in man and animals is followed by a sketchy explanation of the way in which the body reacts to infection and a long chapter on arthritis. The author seems to assume a bacterial basis for most arthritic conditions and claims that bacteria became pathogenic only with the appearance of the vertebrates. (The most likely explanation of this improbable claim would be the misreading of a sentence in Simpson's book *Life of the Past*.) Periodontitis, tuberculosis, syphilis and some other infections are briefly considered; in the case of the last the author, after some hesitation, accepts the view that it was brought to Europe from America in the 15th century. He then deals at some length with the outlines of mutilated hands which appear on the walls of some caves and, rejecting all other suggestions, he explains them as amputations effected therapeutically to arrest gangrene following paronychia or Raynaud's disease.

The longest chapter concerns itself with trepanation and the syncytial Y. He holds that trepanation had no ritual significance (except possibly in the Loire region) but had invariably a therapeutic objective. He finds some interesting parallels to the syncytial Y among living peoples.

The book is profusely illustrated, but some plates add little to the text. The work ends with a glossary and a bibliography. The latter gives a useful list of French and Spanish work in this field; the former arouses curiosity about the readers for whom the book was written. Many names familiar to anybody with an elementary knowledge of biology are glossed; for example, humerus, femur. Others in everyday use in the medical world are glossed, often inaccurately; for example, glioma—a swelling of the nerves! Pathological conditions are given names never used in medical works in English; for example, paranitium for paronychia. The translator would seem to be unfamiliar with much of the English medical vocabulary.

Nevertheless, in spite of many shortcomings the work contains much information, especially concerning the author's own observations and conclusions. Its chief defects are its superficial treatment of many topics, its lack of order and critical judgment. It omits any detailed consideration of the confusion caused by the post mortem action of environmental factors on human (and animal) remains and makes no suggestions about topics the further study of which might be most productive. As a serious study of a subject which is attracting increasing attention the book is disappointing. H. HUGHES

EARLY BEHAVIOUR

Brain and Early Behaviour

Development in the Foetus and Infant. Edited by R. J. Robinson. (Centre for Advanced Study in the Developmental Sciences.) Pp. xvi + 374. (Academic Press: London and New York, January 1970.) 100*s*; $15.

THIS book is a collection of nineteen papers from a study group on the brain mechanisms behind early behavioural development in the foetus and newborn infant, under the aegis of the Centre for Advanced Study in the Developmental Sciences being established at Minster Lovell near Oxford.

It was a multidisciplinary group, which included Heinz Prechtl of Groningen speaking on the brain and behaviour mechanisms of the newborn; Bergström of Helsinki on electrical parameters of the brain during ontogeny; Humphrey of Alabama on the neuroanatomical basis for postnatal repetition of human prenatal activity sequences; Schulte of Göttingen on nerve conduction velocity in relation to myelination and maturity; Wolff of Boston on motor development; Dittrichova of Prague and Petre-Quadens of Antwerp on cerebral sleep patterns; Bronson of California and Bower of Harvard on the development of vision; Lipsitt of Rhode Island and Papousek of Prague on learning and conditioning in the foetus; Ploog of Munich on primate studies; Sander of Boston on the organization of behaviour; and Robinson of London on cerebral hemisphere function in the newborn. Seventy-five pages are occupied by discussion after the papers. As usual with published symposia, the discussions are difficult to read, but much interesting material would have been lost if they had been omitted. The book is intended to analyse early behaviour from the viewpoint of underlying brain mechanisms, and is expected by Robinson, who edited the book, to interest neurologists, paediatricians, psychologists and biologists.

The section on the smile of the baby in his first six weeks revealed the usual confusion about its interpretation and significance. When it seemed to be suggested that the baby's smile in response to the mother's overtures, which include visual, kinetic and auditory stimuli, need not be distinguished from facial movements during sleep, Heinz Prechtl aptly asked what the sleeping baby was likely to be dreaming about. As always with these psychological studies, no mention was made of the relationship between the age of smiling and the maturity (and perhaps the personality) of the infant. After all, any paediatrician interested in the development of the infant knows that all mentally defective infants, such as mongols, are later than the average baby in beginning to smile; it would not be surprising if an infant with a high developmental potential were to begin to smile earlier than usual. I have personally seen three such infants who smiled in response to maternal overtures within four days of birth, and who a few days later were vocalizing well in association with the smile. One might add that, as always with these studies, there was no mention of the developmental features which precede the smile—the baby's intent regard of the mother as she speaks to him, his opening and closing of the mouth, his bobbing of the head up and down—until gradually the real smile becomes obvious.

I feel confident that the book will achieve its object. It is bound to be of interest to the neurophysiologist and to those paediatricians who are interested in developmental neurophysiology and in the application of the sophisticated apparatus and the computer so necessary for these studies. It would have been a pity if all the interesting information and provocative thoughts in it had not been made available to those not able to attend the meeting. I am glad to have the book in my departmental library. R. S. ILLINGWORTH

THE MEGALOBLAST

The Megaloblastic Anaemias

By I. Chanarin. Pp. xv + 1,000. (Blackwell (Scientific): Oxford and Edinburgh, 1969.) 200*s*.

THOUGH preceded by the classic clinical papers of Combe, Addison and Biermer, Ehrlich's description of the megaloblast in 1880 was the first definitive pointer to the complex of diseases so ably marshalled by Dr Chanarin. Some idea of the magnitude of his undertaking may be gauged by the references, which total more than three thousand. It will therefore be appreciated that this is a tremendous source of information, dealing in its thirty-six chapters with the basic chemistry, nutritional aspects and metabolism of cobalamins and folates, the physiological and morphological effects of lack of these substances in man and other organisms, and the various clinical disorders associated with megaloblastic anaemia. Such diversification as illustrated by this book highlights the dilemma of the modern haematologist who must range over so many disciplines that he is in danger of becoming a jack-of-all-trades; but Chanarin has mastered the multidisciplinary approach and is particularly well qualified to do so in the sections dealing with folate metabolism, the FIGLU test and the estimation and function of intrinsic factor, in all of which he has made important contributions. This is the first major attempt to synthesize a detailed and comprehensive account of the megaloblastic anaemias and it is remarkable that it has been accomplished by one author.

The diagrams and illustrations are on the whole of high quality, but the megaloblasts facing pp. 352 and 358 do not have the impact of colour—essential for finer diagnostic distinctions. The erythroblasts opposite p. 370 would not be accepted as megaloblastic by every haematologist. One wonders whether the figure on p. 460 (racial distribution of pernicious anaemia) is relevant enough for inclusion, particularly because it is partly contradicted by more valid data in the following pages. A final point of criticism is of the thread of argument on pp. 818 and 819, concerning the cause and the diagnosis of megaloblastic anaemia in pregnancy; somebody familiar with this problem can follow the text, but to the uninitiated the presentation might seem contradictory and the argument circular. These points are minor, as are also the extremely few bibliographic errors. The general format and printing are of the usual high Blackwell standard and the price is reasonable.

There is much here for the biochemist, biologist and nutritionist, but the chief appeal of this major work of reference is to the medical profession, in the clinic as well as the laboratory. Anybody doing research on megaloblastic anaemia or studying for a higher qualification in haematology will find this book essential reading and it should be in every department of haematology.

H. B. GOODALL

DEFENSIVE NETWORKS

The Reticulo-endothelial System

By A. E. Stuart. Pp. xi + 255. (Livingstone: Edinburgh and London, 1970.) 120*s*.

THIS book is the first general account in the English language of the system of cells throughout the body which plays an important part in defence. It is written by a pathologist who has made important contributions to knowledge of this system, known as the reticulo-endothelial system (RES).

The author starts by describing in some detail the anatomy of the RES; the section on pulmonary macrophages is particularly good. Next, there is a brief but intelligible account of the handling of antigens and iron, followed by an outstanding review of work on stimulation and depression of the RES, which gives special attention to the effects of lipids, and then there is a brief note on the induction of vascular disease. The chapter on cellular immunity in bacterial infections is of an equally high standard.

There follow adequate descriptions of intracellular killing of bacteria, and of the reaction of the system to virus infection. In his account of the macrophage in culture, the author has chosen to be rather selective; much of the work described is his own. This is perhaps the only way of producing a readable account of such a diffuse field. The apparent equation of the extended macrophage in tissue culture with the dendritic macrophage *in vivo* is at present an assumption.

Next there is a slightly scrappy summary of a very scrappy subject—the response of the RES to cancer and grafting. The last chapter is a concise account of the comparative anatomy of the RES, with a memorable picture of a contemplative octopus. This chapter also includes a short consideration of discrimination by macrophages.

In a day when savants spend their days counting the number of pico-devils dancing on the end of a microvillus, the catholicity of Dr Stuart's learning is impressive. It is a considerable achievement to have written a book which passes from the post-mortem room, by way of carbon clearance tests and some ultrastructure, to the octopus and the crayfish, and yet which remains a cohesive whole. A single-author book covering such an extent must, as here, vary in depth of treatment. The style is clear and readable, sometimes picturesque. Cilia "beat with purposeful strokes"—of course they do. The pictures are numerous, mostly good and often coloured, and the bibliography is extensive. The production is good and the price is probably fair.

I enjoyed reading this excellent and authoritative text, and can recommend it warmly to honours students in the medical and biological sciences, to postgraduate students, and to pathologists.

IAN CARR

PHYSIOLOGY OF FISHES

Fish Physiology

Edited by W. S. Hoar and D. J. Randall. Vol. 1: Excretion, Ionic Regulation and Metabolism. Pp. xiv + 465. Vol. 2: The Endocrine System. Pp. xiv + 446. (Academic Press, New York and London, November and December, 1969.) 215*s* each.

FOR one whose first ideas about comparative physiology were stimulated by Hogben's book of that title during the twenties, it is both amazing and delightful to see, reviewed in these books, something of what has been achieved during forty years, just within one group, even one as diverse as the fishes. It is almost equally amazing to see what has been done in the much shorter time since Dr Margaret Varley edited *The Physiology of Fishes*.

Some of the more recent work will have been stimulated by Dr Varley's book, as a convenient reference and review, just as this new series will stimulate students and more senior workers during the next ten years. The subject is, however, intrinsically fascinating, if only because of the diversification of fish species over almost the whole range of aquatic habitats, and the interest of biologists of many kinds seems assured. More specific will be the debt of fisheries research workers, although one would like to think that to some extent this has been paid in advance by that same process of stimulation, and it is good to see among the list of authors already identified several who have worked or still work in recognized marine and fisheries research laboratories, or who have had definitive connexions with them. Fisheries research has achieved more than is often realized, perhaps, but it is necessarily a slow business, and it was perhaps especially slow in realizing the necessity for understanding fish behaviour and its physiological basis. Recently, some useful advances have been made by fisheries scientists in both, but there is far to go and progress must depend greatly on the work of academic colleagues. It is good that this series of volumes, practically all of which promise to be relevant in fisheries terms, is intended to include a section on behaviour itself.

The first volume is devoted to aspects of metabolism: ionic regulation and osmosis, excretion, intermediary metabolism, nutrition and energy requirements, and the like. There is a full account of the physiology of the lower vertebrate kidney, with an introductory chapter on the body compartments and the distribution of electrolytes, and smaller sections on the effects of salinity and on salt secretion. The second volume is devoted to endocrinology although, in spite of the reasoned apology, it will surprise many that the endocrinology of the gonad has been deferred for volume three (and of the pineal gland for volume four) if only because of the known interrelations of the endocrine system. There is a major section on the pituitary, including a separate chapter on the neurohypophysis, with smaller sections on prolactin, the endocrine pancreas, the caudal neurosecretory system and the ultimo-branchial glands, together with thyroid control and the adrenal cortex (although not the medulla). While noting the author's view that an exhaustive review of thyroid function was neither possible nor desirable, it is also noteworthy that reference is made here (and elsewhere) to early literature on chemical identification of hormones with little or no evaluation of the earlier test procedures adopted, although there is at least an acknowledgment in the chapter on the adrenal cortex of the considerable analytical developments of the past decade.

As a whole, however, these first two volumes are admirable, and promise greatly for the remainder, as one would expect of the editors. They have set out their hope that this series of six volumes "will prove as valuable in fisheries research laboratories as in university reference libraries and that it will be a rich source of detailed information for the comparative physiologist and the zoologist as well as the specialist in fish physiology". I think it will, and I expect that it will be found in all relevant libraries, in spite of the heavy price that has to be paid.

C. E. LUCAS

NEW WORLD FLORA

Vascular Plants of the Pacific Northwest

Part 1: Vascular Cryptogams, Gymnosperms, and Monocotyledons. By C. Leo Hitchcock, Arthur Cronquist, Marion Ownbey and J. W. Thompson. Pp. 914. (University of Washington Press: Seattle and London, November 1969.) 238*s*; $25.

THE recent publication of part one now completes this magnificent and already well known flora, the other four parts (each worthy of being called a volume) having appeared in reverse order during the past fifteen years, starting with Cronquist's Compositae.

The Pacific North-West, as defined by the authors of the flora, is an extensive area of territory covering the states of Washington, northern Oregon, Idaho north of the Snake River plains, the western mountainous part of Montana and southern British Columbia. Some 4,000 species of vascular plants are known to be indigenous here or to have been introduced and these have now been fully dealt with in the five parts. As the title indicates, part one includes the vascular cryptogams (ferns and fern allies), gymnosperms and monocotyledons, most of them dealt with by the senior author C. L. Hitchcock. Users of this and probably the other parts of the flora may possibly be confused by the circumscription and nomenclature of the divisions and classes of the higher plants. For instance, here the name Pinophyta is used for Gymnospermae, Magnoliophyta for Angiospermae and Liliatae for Monocotyledonae, following the recent proposals of Cronquist *et al.* in *Taxon*, **15**, 1966. The sequence of monocotyledon families also follows Cronquist's *Evolution and Classification of Flowering Plants* (1968) and might seem strange to those not already familiar with this treatise. Besides the usual keys to families, genera and species and rather full descriptions, complete "regional" synonymy is given together with details of chromosome number (very frequently known), "genuine" vernacular names and information on distribution and ecology. Finally, notes on infraspecific variation have been added. Following the (unfortunate ?) tradition of most temperate floras, no matter how elaborate, no specimens are, however, cited other than type material.

Perhaps two features above all contribute to the usefulness of this particular part. The first of these is the excellence of the illustrations by J. R. Janish. Practically every species has been illustrated by simple but extremely clear and accurate line drawings, depicting habit and diagnostic characteristics. The second is the inclusion of special keys. One to the grasses of the area (again illustrated) is based purely on vegetative features and will be of great potential use to pasture ecologists and agriculturists who so often must, of necessity, identify sterile material. There is also a key to aquatic plants (all vascular groups included), again chiefly on vegetative characters.

This volume, being the last and largest part of the flora to appear, includes several sections relating to the work as a whole. There is, for instance, an index to all the plant families, a glossary and a corrigendum to the other parts. Finally, there is a complete index to vernacular, generic and specific names.

The sheer bulk of this flora means that it will serve chiefly as a work of reference, but the thoroughness of its production will certainly ensure for it a status and value far above that of a mere regional flora, for many years to come.

BRIAN T. STYLES

QUANTUM CHEMISTRY

Methods of Molecular Quantum Mechanics

By R. McWeeny and B. T. Sutcliffe. (Theoretical Chemistry—A Series of Monographs, Vol. 2.) Pp. ix+307. (Academic Press: London and New York, December 1969.) 84*s*; $13·50.

WRITTEN for a far more sophisticated and exacting readership than the first volume in the series, this is a book in which even the most experienced quantum chemist should find a great deal of value. A rigorous yet economical exposition, characterized throughout by refreshing critical insight, it has all the qualities one would expect of its authors.

Being designed "for students specializing in theoretical chemistry or molecular physics", it uses techniques which go well beyond the repertoire of the average chemist. It is certainly a work of consolidation rather than primary instruction. At first sight, much of the analysis will seem formidable to student readers; and, while those who do battle with the difficulties will find themselves very well rewarded, I think this book will probably be more popular with teachers of quantum chemistry than with their students.

Together with two appendices, the first two chapters present a brisk survey of the general principles and theorems of wave mechanics, illustrated by reference to one- and two-electron systems. Next comes a careful account of the various operators used in formulating many-electron antisymmetrized wave functions.

Having completed the usual preliminaries (though by no means always in the usual way), the authors then provide a most welcome discussion of electronic charge distribution, including, of course, a description of density matrices.

The next three chapters deal in turn with the Hartree–Fock theory and its principal elaborations, with valence–bond theory, and with various recent developments (generalized product functions; variation–perturbation theory for group functions; cluster development; correlated pair functions).

A chapter on electrical and magnetic effects is supplemented by a quite substantial appendix dealing with relativistic terms in the Hamiltonian operator.

The book concludes with a description of some typical molecular calculations. This is the only chapter in which any numerical results are discussed.

It could perhaps be argued that much of the material in this book could have been expounded accurately and effectively in a simpler way; but this was clearly not the authors' intention, and they are to be congratulated on producing a contribution to the didactic literature of quantum chemistry that is really distinctive.

E. THEAL STEWART

Obituaries

Dr Peyton Rous

EXPERIMENTAL pathology and cancer research, and indeed the whole of biological and medical science, have sustained immense loss from the death, on February 16, 1970, of Francis Peyton Rous, at the age of 90. His special fields will never be the same without him. Yet our main emotion must be of gratitude for his long life and epochal contribution.

Rous's mother was descended from Huguenots who had settled in Virginia after the Edict of Nantes; and his father was a Baltimorean of English forebears. Reading of his early life evokes and recaptures in remarkable degree the spirit of a great period in the history of the United States and, a little later, that of an outstanding phase in American medicine during the early years of the century. After graduating MD at the Johns Hopkins Medical School in 1905, Rous's interests very early turned to research, with a period at Ann Arbor under Warthin and later in the Rockefeller Institute, New York, where he spent the great part of his working life in the most happy and congenial of conditions. His move to the Rockefeller was a stroke of genius on the part of Simon Flexner, who accorded him complete freedom and every encouragement, a privilege which Rous thenceforth ever valued and later recorded on many occasions.

Between 1907 and 1910 Rous made a wonderful start, with papers on lymphocyte physiology, haematology, the cerebrospinal fluid and tissue transplantation. Very soon there came the stroke of fate. In the words of O. H. Robertson, "One day a chicken fancier came in to Rous's laboratory bringing a fowl with a large lump on its leg. Concerned for his flock, this man had taken the fowl to several unresponsive pathologists. Rous saw that the lump was a tumour and in a class of animals unstudied in such relation". The tumour proved to be a spindle-cell sarcoma, which Rous was able to transmit to other fowls of the same inbred stock, not only by grafting but also through the injection of cell-free filtrates. The times must have been propitious, following Ellermann and Bang's description of an apparent leukaemia virus in 1908; yet Rous's discovery was a monumental and key event in the history of cancer research.

The Rous agent, as it came to be called, also seemed to be viral in nature, with extraordinary specificity in transforming normal cells into the exact replica of the sarcoma cells from which it was derived. Later, Rous and his co-workers uncovered other avian oncogenic viruses, each again with its own individual transforming property. Especially with J. B. Murphy, Rous studied the growth of such tumours and viruses in the avian embryo, perhaps the earliest use of this technique, and an example of the freshness and originality which characterized so much of his work and still exert their influence.

There is evidence that these discoveries were not perhaps fully appreciated at the time, as was seen from a species of metaphysical pathology on the part of the orthodox, according to which the tumours, although sarcomata, could not be tumours since they were virus-induced. Rous was also disappointed by his failure, after strenuous efforts, to demonstrate any kind of viral transmission of cancer in mammals. For some fifteen years he then spent his energies in more physiological pursuits, and this period embraced a wide variety of classical papers. Outstanding topics were the preservation and transfusion of blood, with practical application in both the First and Second World Wars by means of the Rous–Turner formula; the genesis of gallstones and the relation of blood destruction to bile pigment output; liver function in many aspects; and the measurement of hydrogen ion concentration in living tissues. Throughout his work Rous showed rare technical ingenuity, perhaps the most famous instance being his isolation of Kupffer cells in pure culture by loading them with particulate iron and collecting them from liver perfusates with the aid of a magnet. Another instance ahead of its time was his plating method for individual cells.

Rous's wholehearted and enthusiastic return to the cancer field was prompted by two personal episodes. A few years before, W. E. Gye had made certain claims as to the constitution of the Rous agent. Although these claims were not confirmed, their investigation had the undoubted effect of bringing the filterable sarcomata into a new prominence, and through this development Rous was both encouraged and stimulated—something for which he always expressed much gratitude. Secondly, the late Richard E. Shope had persuaded Rous to embark on a full-scale investigation of the so-called Shope rabbit papilloma virus recently discovered in the cottontail rabbit. Hence it came that Rous entered a quite new and highly productive phase which endured to the end of his life. Of special and lasting value were his studies of the biological interactions between chemical carcinogens and neoplastic viruses, and the generation of highly malignant carcinomata in the rabbit on the basis of the viral papillomas. In part, this experimental work led to, and was intertwined with, a fundamental conception (with Friedewald) which ranks, in the view of many, as perhaps the most profound of Rous's contributions; namely, the dissection of the carcinogenic process into two main stages of initiation and promotion. Independently advocated by Berenblum, the hypothesis remains influential and may still receive its explanation in chemical and cytological terms.

Dr Peyton Rous

At the time of the discovery of the avian tumour viruses, and for several decades thereafter, technical resources were inadequate to penetrate their structure and biochemistry. Although much remains to be done, great advances are in prospect which might dramatically or even decisively illumine the whole of the cancer problem. Meantime, in his later years Rous experienced great excitement from many discoveries on the part of others demonstrating the unexpected quality of the Rous virus, enhanced or in association with other agents, to break the species barrier and to evoke tumours in many species, both avian and mammalian; and secondly, from the immense resurgence of tumour virology to which his lone observation of 1910 had pointed the way.

Aside from his own publications (some 300 in all) Rous also contributed to scientific presentation and acted as editor of the *Journal of Experimental Medicine* for over thirty years. His width of cultivation could also be seen in most amusing and lighthearted essays, as on tactlessness, and the lamentable decline in self-satisfaction. Honours descended upon him from every part of the new world and the old, culminating in the Nobel Prize for Medicine (jointly) in 1966. For many reasons of domesticity and friendship he had special ties of affection for England and, with much other recognition, treasured his Linacre lectureship at Cambridge, his honorary fellowship of Trinity Hall, the Walker Prize of the Royal College of Surgeons, and his foreign membership of the Royal Society. In admiration he would refer to "those wonderful powder-blue volumes" (the Scientific Reports) of the Imperial Cancer Research Fund.

Rous was a true worker at the bench, yet believed that the experimental pathologist and the artist have much in common. He described his recreation as "relishing life", and this he did to the full. When the history of cancer research comes to be written, he will rank with the highest in honour.

Correspondence

Non-ideal Gas

SIR,—In view of the continuing flurry of polemics over the rights and wrongs of CS "gas", it is absolutely vital that the slender body of available factual evidence relating to the toxicity of the material be described with dispassionate accuracy. In the circumstances we have no alternative but to apologize and to assume full responsibility for a premature conclusion in our work on the toxicity of CS, which was reported in your excellent article[1]. Investigations carried out since these preliminary results were presented at the BSSRS symposium last November have revealed that the cytotoxic effects of injected CS on kidney and liver cells in mice are by no means clear-cut, and also that the primary locus of short-term toxicity resides in neither of these organs. In any case, this histological work is likely to prove irrelevant to the use of CS in riot control.

Some studies of CS toxicity have been published. Punte and his associates[2] at Edgewood Arsenal, Maryland, derived an approximate value for the LD$_{50}$ of 8 mg/kg body weight by intravenous injection into rabbits. These authors also showed that inhalation of CS aerosols by pigeons and by various mammals could cause death, and included LCt$_{50}$ values. Pulmonary oedema and haemorrhage of the adrenal glands were sometimes found, especially at high inhalation doses. Particles of CS also produced necrosis at sites of impact in both the gastrointestinal and respiratory tracts. As far as can be gathered, all experimental animals which have been subjected to CS aerosols were protected externally by hair or feathers. The comparison of such findings with the analogous situation in man is not therefore straightforward. Other studies have been carried out at Edgewood Arsenal and elsewhere, but, without denying the importance of making such studies public, the deduction that failure to publish automatically implies the discovery of disturbing features on the part of the material is a little facile.

When CS is employed in riot control, two things may happen. First, an amount of the agent may enter the body, and second, the subject may suffer cellular injury, most probably in the respiratory tract. If the Himsworth Committee confirms its original intention to consider CS as a drug, then the quantitative relationships between dose, effectiveness of action and toxic hazard become the crucial issue. The degree of exposure of any individual in a crowd can bear no resemblance to the defined dosage of a drug taken by a patient under the care of his physician. Moreover, very wide variation in the susceptibility of people to CS has been reported[3,4]. With knowledge of the action of poisons increasing rapidly and with techniques for detecting cytotoxicity becoming more sophisticated, we may soon find that any anti-personnel chemical causes some tissue damage somewhere, and hence constitutes a hazard to health. If experimental support for this concept is forthcoming, a humane society may have no alternative but to abandon the use of these materials entirely.

Yours faithfully,

G. R. N. JONES

Syn and Anti

SIR,—In discussing the molecular conformation of nucleosides (*Nature*, **225**, 1190; 1970), your Biomolecular Structure Correspondent states that the pucker of the sugar ring in 4-thiouridine (Saenger and Scheit, *Angew. Chemie*, **8**, 139; 1969) is C2′ endo whereas the original paper states that the pucker is C3′ endo. In the case of pyrimidine nucleosides with a C3′ endo pucker the energy minimum for a *syn* conformation is not as low as that for the *anti* conformation, which makes the 4-thiouridine structure perhaps even more interesting than your correspondent suggests.

Yours faithfully,

HERBERT R. WILSON

Carnegie Laboratory of Physics,
University of Dundee,
Dundee.

Our Biomolecular Structure Correspondent writes: A typical C2′ endo sugar has C2′ $\sim$0·5 Å out of the plane defined by C1′, O1′ and O4′, on the same side as C5′, and C3′ $\sim$0·1 Å out of plane on the other side. In a C3′ endo sugar the out of plane displacements of C2′ and C3′ are reversed. In 4-thiouridine both C2′ and C3′ are displaced on the same side of the plane as C5′ by 0·3 Å and 0·8 Å respectively, and this rather unusual conformation might be described as "C2′ endo, C3′ endo". However, from the point of view of the orientation about the sugar-base link, the position of C2′ and its attached hydrogen is of particular importance and it was in this context that I described the conformation as approximating to C2′ endo. It may be that this description left an impression over-generous to the computerized seekers after energy minima; nevertheless, theirs is never the most rewarding of pursuits and I feel the 4-thiouridine observation provides them with some modest crumb of comfort which it would be churlish to ignore.

Butterfly Blues

SIR,—In Peter Scott's impressive catalogue (*Nature*, **225**, 1174; 1970) of the conservation projects of the World Wildlife Fund, one small inaccuracy needs correcting. The Large Blue butterfly, *Maculinea arion* Linn., should not be described as a species "threatened with world extinction". I can testify to its continued prevalence over much of the Swiss Alps and the Jura, and five years ago I recall finding it equally common in the foothills of the Caucasus at Sochi.

This makes it none the less desirable to save *M. arion*, if possible, from extinction in Britain. And I would like to stress the special value of *comparative* studies of the environmental pressures on such species, in areas where they are disappearing and in others where they continue to flourish. The need for this type of study is liable to be neglected—possibly because, involving prolonged field work by identical methods in more than one country, it may frequently demand more time and money than the amateur can give it. I hope the World Wildlife Fund will step in to support such an approach where it is required.

Yours faithfully,

C. GARRETT-JONES

c/o World Health Organization,
1211 Geneva 27,
Switzerland.

Antifertility Intermediate

SIR,—Male antifertility with 2,3-epoxypropanol was disclosed in two letters (*Nature*, **226**, 86 and 87; 1970). Jackson *et al.* suggest glycidol as an active intermediate of α-chlorohydrin. We propose an opposite mechanism—that glycidol is partially converted to α-chlorohydrin; both hypotheses consider the greater chemical reactivity of glycidol. Until these letters, no non-chlorinated related substances, including other halogens, were shown to be effective[1]. It seems more probable that glycidol would react with hydrochloric acid in the stomach to form α-chlorohydrin, glycerol and other substances—which explains the higher amounts required for activity. Hahn in his letter assumes the oxygen bridge of the active epichlorohydrin opens, in the rat, to form α-chlorohydrin, whereas opening the epoxy bridge of the active glycidol would yield inactive glycerol. The reactive glycidol, as we propose, opens up to form α-chlorohydrin in addition to glycerol.

The compound at the site of antifertility activity may indeed be α-chlorohydrin. Although 25–32 per cent of the compound is given off as $^{14}CO_2$ (labelled at the middle carbon) another 16–26 per cent is excreted in urine as the parent compound[2].

Yours faithfully,

R. J. ERICSSON
G. A. YOUNGDALE

Announcements

University News

Dr George Chadwick has been appointed to the second chair of town and country planning in the **University of Newcastle upon Tyne.**

Dr Ralph Riley, Cambridge Plant Breeding Institute, has been appointed a special professor in the Department of Botany, **University of Nottingham.**

Dr D. J. Greenland, University of Adelaide, has been appointed head of the Department of Soil Science, **University of Reading,** in succession to **Professor E. Walter Russell.**

Appointments

Mr R. H. Weir, director of the National Gas Turbine Establishment, has been appointed director of the **National Engineering Laboratory** in succession to **Mr F. D. Penny. Mr I. M. Davidson,** deputy director of the National Gas Turbine Establishment, has been appointed director.

In a series of appointments at the **Oak Ridge National Laboratory, Dr Floyd L. Culler** has been made deputy director from the middle of May—he will succeed **Dr H. G. MacPherson,** who is to become professor of nuclear engineering at the University of Tennessee. Four associate directors have also been appointed and are: **Dr James L. Liverman** (biological and environmental sciences); **Dr Arthur H. Snell** (basic physical sciences) who has been at the Oak Ridge National Laboratory since its beginning in 1958 and who has been responsible as an assistant director for work on controlled nuclear fusion; **Dr Donald B. Trauger** (reactor engineering sciences) who has been since 1964 director of the laboratory's advanced gas cooled reactor programme; and **Dr Frank R. Bruce** (administration). The laboratory has also set up a new Ecological Sciences Division under the direction of **Dr Stanley I. Auerbach.**

Miscellaneous

Dr Charles Stark Draper, the founder of the Instrumentation Laboratory (now the Draper Laboratory) at MIT, has been awarded the fifth Founders Medal of the National Academy of Engineering.

P. P. Feofilov has been awarded the C. I. Vavilov gold medal of the USSR Academy of Sciences for his work on spectroscopy and luminescence of activated crystals.

The Meldola Medal for 1969 has been awarded to **Dr P. W. Atkins,** Oxford, in recognition of his work in theoretical chemistry.

The Organisation Internationale de Lutte Biologique (OILB) is to be enlarged and restructured to form the new International Organization for Biological Control, to promote research into biological control in the broadest sense throughout the world. Provision will be made in the new statutes for individual, institutional and supporting membership, and for the creation of largely autonomous regional sections on a biogeographical basis.

ERRATUM. In the article "New Finds at the Swartkrans Australopithecine Site" by C. K. Brain (*Nature*, **225**, 1112; 1970), a penultimate sentence should be added to the paragraph beginning "In 1958 . . . " on page 1113: "A concentration of coarse material is visible in the outer cave filling, against the N. wall, just east of the face worked by Broom and Robinson".

ERRATUM. In the article "A Comparison of Marijuana Users and Non-users" by Norman E. Zinberg and Andrew T. Weil (*Nature*, **226**, 119; 1970), the third sentence in the first column on page 122 should be "There were no signs of overt intellectual deterioration in the C interviewees, . . .".

ERRATUM. The title of the communication by Mepham and Lane (*Nature*, **226**, 180; 1970) was given incorrectly on the contents page. It should read: "Adaptive significance of the sculptured exine of pollen".

ERRATUM. The book *Matrix Algebra for Business and Economics* was incorrectly priced at 40*s* (*Nature*, **225**, xxxii; 1970). It costs 140*s*.

International Meetings

May 19–21, **Non-ferrous Metals: the Next Fifty Years,** London (The Secretary, the British Non-Ferrous Metals Research Association, Euston Street, London NW1).

June 9–12, **Thirteenth Annual Meeting of the Canadian Federation of Biological Societies,** Montreal (Dr K. K. Carroll, Biochemistry Department, University of Western Ontario, London 72, Canada).

June 22–July 31, **Advanced Study in Gerontology** (summer institute), Los Angeles (Summer Institute Coordinator, Gerontology Center, University of Southern California, University Park, Los Angeles, California 90007, USA).

July 6–31, **Community Mental Health and Aging** (summer institute), Los Angeles (Summer Institute Coordinator, Gerontology Center, University of Southern California, University Park, Los Angeles, California 90007, USA).

September 1–4, **Hydraulic Transport of Solids in Pipes**, Coventry (Mr H. S. Stephens, Organizing Committee Secretary, 1st ICHTSP, British Hydromechanics Research Association, Cranfield, Bedford).

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Wanted: Furnished, 3-bedroomed, centrally heated house or flat for American physician and family, August 1970–71. Close to Mill Hill and within half hour from central London. Rent £50–£70 month. Please contact Dr A. Haase, Building 10, Room 11N-218, Bethesda, Maryland 20014, USA.

Wanted: British medical scientist and family require 2-bedroomed flat near Rockefeller University, New York, for 1 or 2 years from October 1970. Can exchange 3-bedroomed furnished house with garage and central heating in Ruislip Gardens (West London). Very conveniently situated for public transport. Please contact Dr T. J. Peters, Department of Medicine, Royal Postgraduate Medical School, Ducane Road, London W12.

Wanted : Furnished, centrally heated house or flat in or near northern London, for research social scientist and family (two children). Prefer one year lease starting between mid-June and mid-July 1970. Please contact Dr R. Turner, Department of Anthropology, University of British Columbia, Vancouver, BC, Canada.

Wanted : From August/September 1970, 3/4 bedroomed house in Bristol: convenient for university and Langford. Please contact Dr D. F. Kelly, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA.

Wanted : 2–3 bedroom furnished house, Cambridge, 1 year beginning August 1, 1970, for professor and family. Prefer central heating; will consider 15 guineas p.w. Please contact M. Freedman, Anthropology Department, Syracuse University, Syracuse, New York 13210, USA.

Wanted : Furnished house or flat in or near Cambridge, England, for professor, wife and 2 children from September 1970 to September 1971. Central heating and 3 bedrooms preferred. **Vacant :** Can offer for rent or exchange 3-bedroomed house in Seattle, Washington, for same period. Please contact Dr Peter Hobbs, 2815, 105th Ave, SE, Bellevue, Washington 98004, USA.

Vacant : In central London, furnished 3-bedroom house, library, sitting room, dining room, well-equipped kitchen, full bathroom, second toilet, lovely small garden. Excellent bus and tube connexions to all areas. Available from late summer 1970, preferably for periods of more than six months. Please contact R. B. Fisher, 26 St Paul's Rd, London N1.

British Diary

Monday, April 27

Apprenticeship and Industrial Training (6 p.m.) Mr Cyril R. English, Royal Society of Arts, at John Adam Street, London WC2. (Second of three Cantor Lectures on Training for Industry.)

Contact Problems in Machines using Thyristor Assisted Communication (5.30 p.m.) Professor J. J. Bates, Mr S. Stanway and Mr R. F. Sansum, Institution of Electrical Engineers, at Savoy Place, London WC2.

Escalators and Travolators (6 p.m.) Mr C. W. Hardie, Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Gunn Domain Logic (5.30 p.m.) Dr H. L. Hartnagel, Institution of Electrical Engineers, at Savoy Place, London WC2.

Quasi-stellar Objects (5.30 p.m.) Professor G. Burbidge (University of California), University College London, in the Physics Theatre, Gower Street, London WC1.

The Evolution of a Microbial Metabolic Pathway (5.30 p.m.) Professor Roger Y. Stanier (University of California), University College London, in the Botany Theatre, Gower Street, London WC1.

Tuesday, April 28

Biological Effects of Pollution in the Sea (two-day meeting) Royal Society at 6 Carlton House Terrace, London SW1.

Capacitors (10 a.m. symposium) Institution of Electronic and Radio Engineers, Components and Circuits Group, at 9 Bedford Square, London WC1.

Modulated Sub-carrier System for Attenuation Measurement at X-band (5.30 p.m.) Mr F. Warner, Institution of Electrical Engineers, at Savoy Place, London WC2.

Recent Developments in Tropical Agriculture (10 a.m. symposium), Society of Chemical Industry, Agriculture and Pesticides Groups, at 14 Belgrave Square, London SW1.

Selection of Materials for Marine Structures (6 p.m.) Mr H. Gibbs, Society of Chemical Industry, Plastics and Polymer Group, at 14 Belgrave Square, London SW1.

The Unicellular Blue-Green Algae—a Little Known Group of Bacteria (5.30 p.m.) Professor Roger Y. Stanier, University College London, in the Botany Theatre, Gower Street, London WC1.

24-Channel PCM (6.30 p.m.) Mr A. Stevens, Institution of Electronic and Radio Engineers, jointly with the Institution of Electrical Engineers, at the Civic Centre, Duke Street, Chelmsford.

Unsaturated C18 Acids—Their Synthesis and Properties (6.15 p.m.) Dr F. D. Gunstone, Society of Chemical Industry, at 14 Belgrave Square, London SW1.

Vehicle Handling Qualities, Professor F. D. Hales; **Measurement of Vehicle Handling by Tethered Testing,** Mr N. F. Barter (6 p.m.) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Wednesday, April 29

Electrical Power Installations in Warships (5.30 p.m.) Mr H. C. Fitzer, Institution of Electrical Engineers, at Savoy Place, London WC2.

Ionospheric Research by Means of Oblique Incidence Sounders (5.30 p.m.) Mr P. Bradley, Institution of Electrical Engineers, at Savoy Place, London WC2.

Marketing within the Plastics Industry (5 p.m.) Plastics Institute, at the Great Western Royal Hotel, Paddington.

Non-standard Analysis—II. Compactness Arguments in Function Theory (5.30 p.m.) Professor Abraham Robinson, University College London, in the Engineering Theatre, Gower Street, London WC1.

Quasi-stellar Objects—II (5.30 p.m.) Professor C. Burbidge, University College London, in the Physics Theatre, Gower Street, London WC1. (Further lecture on April 30.)

Scanning Circuits for 100° Colour Tubes (6 p.m.) Mr K. E. Martin, Institution of Electronic and Radio Engineers, Communications Group, at 9 Bedford Square, London WC1.

The Origin of the Earth's Magnetic and Gravitational Fields (5 p.m.) Dr R. Hide, Royal Meteorological Society, at 49 Cromwell Road, London SW7. (Symons Memorial Lecture.)

Thursday, April 30

Cooperation between Lymphocytes in the Immune Response (2.30 p.m. discussion meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

Microprogramming and Processor Design (5.30 p.m.) Professor M. V. Wilkes, Institution of Electronic and Radio Engineers, Joint IEE/IERE Computer Group, at the Institution of Electrical Engineers, Savoy Place, London WC2.

The Hydrogenation of Fatty Acids (6.30 p.m.) Dr Brangwin, Institution of Chemical Engineers, at Whitehaven College of Further Education, Whitehaven.

Friday, May 1

Logic as the Science of Mathematical Reasoning—III (5.30 p.m.) Professor Abraham Robinson, University College London, in the Engineering Theatre, Gower Street, London WC1.

Spectroscopic Properties of Aromatic Chromophores in Surfactant Systems (1 p.m.) Dr J. Philp, Royal Institution, Photochemistry Discussion Group, at 21 Albemarle Street, London W1.

The Invisible Man (9 p.m.) Professor E. M. Rogers (Princeton), Royal Institution, at 21 Albemarle Street, London W1.

Monday, May 4

Assessing Markets for Entirely New Products (6 p.m.) Mr H. M. Kelner Society of Chemical Industry, at 14 Belgrave Square, London SW1.

London Engineering Congress (four days) Council of Engineering Institutions, at the Royal Festival Hall, London SE1. Theme: The Challenge Facing the Profession in its Services to the Community.

Vacuum Arcs (5.30 p.m. discussion meeting) Institution of Electrical Engineers, at Savoy Place, London WC2.

Annals of the New York Academy of Sciences. Vol. 167, Article 1: Comparative and Evolutionary Aspects of the Vertebrate Central Nervous System. By J. M. Petras, C. R. Noback and 35 other authors. Pp. 1–513. (New York: New York Academy of Sciences, 1969.) $29.50. [32

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire	**£14.0.0** each
United States of America (by air freight)	**$48** each
Canada (by air freight)	**$52** each
Elsewhere overseas by surface mail	**£14.0.0** each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

CATALIN IONIC MODELS AID RESEARCH & EDUCATION

Catalin Ionic models are finding increasing use in major research laboratories, notably in the ceramics, electrical, photographic and metallurgical industries, and in institutes of learning throughout the world.

The range comprises 36 elements in various oxidation states, providing 41 model ions. Being constructed to the same scale they may be used in conjunction with Catalin Covalent models to depict complex ions.

THE AUTONOMIC NERVOUS SYSTEM

An introduction to basic and clinical concepts

By **O. Appenzeller,** *University of New Mexico Medical School, Albuquerque.*

1970. 250 pages. Hfl. 45.-(105s.) ISBN 7204 7010 2

This book deals with the anatomy, physiology and pathology of the autonomic nervous system. Clinical applications are discussed and diseases known to be associated with autonomic dysfunction are reviewed extensively.

CONTENTS: Introduction. Anatomy and histology. Temperature regulation. The neurogenic control of the circulation. Trophic disorders. Sleep and wakefulness. Respiration and disorders of ventilation. Disturbances of water and electrolyte balance and disorders of innervation of the gastrointestinal tract. Circadian rhythms. The autonomic nervous system and the pineal gland. Pain syndromes. The normal pupil and some pupillary abnormalities. Neurogenic control and disorders of micturition. The reflex control of copulatory behavior and neurogenic disorders of sexual function. References. Index.

MUSCLE PATHOLOGY

Introduction and atlas

By **J. Bethlem,** *Laboratory for Neuropathology, Academic Hospital, Amsterdam*

1970. 132 pages. 32 colour pages. Hfl. 32.50 (76s.) ISBN 7204 7012 9

An account of the recent situation in the field of muscle pathology. For easy recognition of the microscopic picture full use of colour photographs has been made.

CONTENTS: Symptomatology of neuromuscular diseases. Preparation of the muscle biopsy. Interpretation of the muscle biopsy. Neurogenic muscle diseases. Muscular dystrophy. Mytonic disorders and the periodic paralyses. Polymyositis. Myasthenia gravis. Glycogen storage diseases. Central core diseases. Nemaline myopathy. Myotubular and centronuclear myopathies. Myopathies with abnormal mitochondria. Colour pictures. Index.

APPOINTMENTS VACANT

UNIVERSITY OF OXFORD

Department of Biochemistry

Departmental Demonstratorship

It is proposed to appoint a Departmental Demonstrator from October 1 next or as soon as can be arranged. The salary will be up to £1,515 p.a. according to qualifications and experience (£1,545 p.a. in the case of medically qualified candidates) and with membership of F.S.S.U. The appointment is for a period not exceeding 3 years in the first instance and may be renewable for a further period up to a total of six years.

The successful candidate will be expected to take part in departmental teaching and to conduct his own research.

Applications (3 copies) including the names of two referees should be sent to the Administrator, Department of Biochemistry, South Parks Road, Oxford, not later than May 15, 1970.

(1557)

MARINE BIOLOGICAL ASSOCIATION

PLYMOUTH

INFORMATION SCIENTIST

required to develop, expand and document the Library's MARINE POLLUTION collection. Duties include literature searching, the compilation and maintenance of bibliographies and indexes, acquisition of relevant publications from the world literature, inquiry work and the provision of current awareness services, etc. Applicants should hold a degree or H.N.C. in an appropriate subject or a qualification in information science, and preferably should have previous experience in information work. Initially the appointment will be for a three-year period, and will be at Assistant Experimental Officer or Experimental Officer level, according to age, qualifications and experience. Salary scale: A.E.O., £683 to £1,454; E.O., £1,590 to £2,006.

Applications, giving full relevant details and naming two referees, should be sent to the Librarian, Marine Biological Association of the United Kingdom, The Laboratory, Citadel Hill, Plymouth, PL1 2PB, Devon.

(1648)

MICROBIOLOGICAL RESEARCH ESTABLISHMENT

Porton, Wiltshire

Head of Cell Biology Section

A Principal Scientific Officer is required to head a unit studying the growth and properties of mammalian cells in relation to their potential use in the production of vaccines. The job involves independent research and participation in collaborative projects of interest to other sections in the Establishment and to outside authorities (e.g. M.R.C., Department of Health and Social Security). A full range of specialized support techniques (e.g. histology, media preparation, electron-microscopy) is available.

Candidates should be experienced research workers and have **either** a 1st or 2nd class honours degree or equivalent qualification in zoology or micro-biology and postgraduate experience in the field of host/parasite relations (e.g. virology) **or** a similar degree or equivalent in biochemistry with postgraduate experience in cytology.

The appointment, on the scale £2,820–£3,902, will be permanent and carries a non-contributory pension. Starting salary could be above the minimum. Alternatively the post could be filled by a Principal Research Fellow (normally for a 3–5 year period) within the scale £2,600–£3,595 with contributory pension under FSSU.

Fuller details of this appointment may be obtained by writing to the ***Civil Service Commission, 23 Savile Row, London W1X 2AA,*** **or by telephoning 01-734 6010, ext. 229 (01-734 6464 "Ansafone" service after 5.30 p.m.). At all times please quote S/7445/U2. Closing date 6th May, 1970.**

(1577)

Lepetit, a leading Italian pharmaceutical company is looking for a

MICROBIOLOGIST/BIOCHEMIST

to take charge of a team already involved in the search for new antibiotics. A considerable degree of independence is envisaged and the candidate will be expected to develop and utilize his own ideas in the screening program. Ideally applicants should have some years postgraduate experience in a relevant field (academic or industrial) and be 25–35 years old, salary will be according to age and experience; knowledge of Italian is not important.

The Lepetit research laboratories, which are situated in Milan, employ about 250 people in a wide spread of scientific disciplines and were responsible for the discovery and development of the rifamycin of antibiotics.

Send curriculum vitae to

Gruppo Lepetit—Servizio Selezione—Ricerca PS/70—
Via Roberto Lepetit, 8—20124 Milano.

(1663)

AUSTRALIAN NATIONAL UNIVERSITY

INSTITUTE OF ADVANCED STUDIES
THE RESEARCH SCHOOL OF PHYSICAL SCIENCES

Director: Professor Sir Ernest Titterton, C.M.G., F.A.A.

CHAIR OF APPLIED MATHEMATICS

Applications are invited for appointment as the Foundation Professor and Head of the new Department of Applied Mathematics, Research School of Physical Sciences.

The new Department of Applied Mathematics will join the six existing Departments (Astronomy, Engineering Physics, Geophysics and Geochemistry, Pure Mathematics, Nuclear Physics, Theoretical Physics) and two Units (Diffusion Research Unit and Electron and Ion Diffusion Unit) within the Research School of Physical Sciences. An eighth Department—Solid State Physics—will be established within the next year. The School of General Studies of the University has Departments of Pure Mathematics, Applied Mathematics and Theoretical Physics.

The new Department will be developed over a period of two to three years to an ultimate staffing level of twelve (including academic staff), with up to ten research students supporting its work. The Head of the Department will be responsible for choosing the staff and developing a research programme in chosen areas of Applied Mathematics. However, it is hoped that there will be a strong link between some of the Department's work and fields of experimental work already under way in Canberra, either within the University (which, in addition to Physics, has Schools of Biological, Chemical, Medical and Social Sciences) or in other research organisations such as the C.S.I.R.O.

The normal salary for a Head of a Department is $A13,000 per annum and there is entitlement to one year's study leave on full pay, plus a grant of not more than $A3,200 towards expenses in every four years. Salaries are currently under review and improvements are expected. Superannuation is on the F.S.S.U. pattern, with supplementary benefits. Reasonable travel and appointment expenses will be paid and assistance provided with housing.

Further information about the position and a summary of conditions of appointment of academic staff may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London, W.C.1.

Applications close on **May 15, 1970.**

(1493)

UNIVERSITY OF MANCHESTER

LECTURER IN BIOLOGICAL CHEMISTRY

Applications invited for this appointment. An interest in proteins is desirable but not essential. Salary range per annum £1,240 to £2,850 but initial appointment will be within range £1,240 to £1,585. F.S.S.U.

Further particulars and application forms (returnable by May 9) from the Registrar, The University, Manchester, M13 9PL. Quote ref: 76/70/NA. (1591)

QUEEN ELIZABETH COLLEGE (UNIVERSITY OF LONDON) CAMPDEN HILL ROAD, W.8

Applications are invited for the post of Lecturer in Pure or Applied Mathematics.

Further particulars from the College Secretary, to whom four copies of application should be sent by May 8. (1640)

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH BUREAU OF ANIMAL HEALTH
Central Veterinary Laboratory, New Haw, Weybridge, Surrey

Duties: Preparing English language abstracts and editorial work for the monthly journal *The Veterinary Bulletin*, which covers world scientific literature on veterinary science.

Qualifications: A degree in a biological science. Ability to write good and concise English essential. Reading knowledge of at least one modern European language, preferably an East European language, desirable.

Salary: In scale £1,071 to £2,809, with provision for superannuation. Starting salary according to qualifications, experience and age. Two extra increments after two years' satisfactory service for applicants aged 32 or under on date of appointment.

Application forms and full particulars from the **Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Nr. Slough, Bucks.**

Closing date for applications: 31 May, 1970.

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH BUREAU OF PLANT BREEDING AND GENETICS
Department of Agricultural Science and Applied Biology, Downing Street, Cambridge

Duties: Duties include preparation and editing of abstracts for the journal *Plant Breeding Abstracts*, classification of biological literature and dealing with scientific inquiries.

Qualifications: Applicants preferred with a botanical or agricultural degree and/or knowledge of or aptitude for foreign languages. Ability to write good English essential.

Salary: In scale £1,071 to £2,809, with provision for superannuation. Starting salary according to qualifications, experience and age. Two extra increments after two years' satisfactory service for applicants aged 32 or under on date of appointment.

Application forms and full particulars from the **Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Nr. Slough, Bucks.** (1650)

UWIST

CARDIFF

UNIVERSITY OF WALES INSTITUTE OF SCIENCE AND TECHNOLOGY

CHAIR IN APPLIED PHARMACOLOGY

(Re-advertisement)

Applications are invited from graduates in Pharmacy, Pharmacology, Physiology or Medicine for a newly created Chair in Applied Pharmacology (Biopharmacy) which is the second Chair within the Welsh School of Pharmacy.

Salary within the professorial range with F.S.S.U.

Requests for further particulars to Personnel Officer (quoting ref. Na.). Applications to be received by 29th May, 1970. (1713)

ASSOCIATED
SCIENTIFIC
PUBLISHERS
LTD.

comprising

ELSEVIER
PUBLISHING
COMPANY

NORTH-
HOLLAND
PUBLISHING
COMPANY

and their affiliated companies in New York, London and Lausanne

wish to appoint a **SENIOR SCIENTIST** to the position of

EDITOR IN CHIEF

who will be responsible for the central planning of new publishing projects and for the coordination of the editorial activities of the five companies. These activities cover the natural sciences and related fields with special emphasis on chemistry, biochemistry, physics, mathematics, geo-sciences, econometrics and the neurosciences.

The A.S.P. Group already has a team of very capable scientists/editors and the person appointed must be able to command their respect on both the personal and professional planes. He should be inventive, aware of the currents in modern scientific research and education, and be capable of exercising sound commercial judgement.

Candidates need not necessarily have had publishing experience although a deep interest in this field, and in the new developments in information transfer, is absolutely essential.

The Editor in Chief should ideally be prepared to take up residence in Amsterdam, although consideration could be given to a London siting.

Those at present earning less than £5,000 per annum are unlikely to qualify for the post.

Applications giving full details of qualifications and experience should be addressed to The Directors, Associated Scientific Publishers, Elsevier House, Jan van Galenstraat 335, Amsterdam-W., the Netherlands. (1652)

RESEARCH AND DEVELOPMENT ESTABLISHMENT

British-American Tobacco Company Limited

require a

COMBUSTION CHEMIST

to study the fundamental chemical and physical processes occurring in a burning cigarette. Applications would be welcomed from Ph.D.'s with relevant experience, which may have included work on physical-organic processes occurring in the oxidation of vapours or solids, heterogeneous catalysis, or computer-model studies of chemical reactors.

The commencing salary will be negotiable according to experience, and will be very attractive to candidates under the age of 35 years.

If you are interested please write or telephone for an application form from:

Mr. N. R. Page,
RESEARCH AND DEVELOPMENT ESTABLISHMENT,
British-American Tobacco Company Limited,
Regents Park Road, Southampton, SO9 1PE
Telephone: Southampton 72466 (1654)

AUSTRALIAN NATIONAL UNIVERSITY

THE JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

CHAIR OF HUMAN BIOLOGY

Applications are invited for appointment to the post of Professor of Human Biology and Head of the Department of Human Biology.

The Department of Human Biology was established on January 1, 1970, and is one of eight Departments in the John Curtin School of Medical Research (Director: Professor F. Fenner, F.A.A., F.R.S.); other departments are Physical Biochemistry, Biochemistry, Clinical Science, Experimental Pathology, Medical Chemistry, Microbiology and Physiology: a ninth Department (of Immunology) is to be established soon.

The Head of the Department of Human Biology will be responsible for the direction and co-ordination of work in the new department and will have full scope to develop a research group devoted to his own interests. A nucleus of the department has already been formed from two small existing groups, Human Genetics (2 academics plus support staff) and Urban Biology (1 academic plus support staff) under the Acting Headship of Professor Fenner.

All departments in the John Curtin School are involved solely in research and postgraduate (Ph.D. and postdoctoral) training; members of staff are not required to participate in undergraduate teaching.

Normal salary is $A13,000 per annum (under review); there is entitlement to one year's study leave on full pay, plus a grant of up to $A3,200 towards expenses, within each four-year period. Superannuation is on the F.S.S.U. pattern, with supplementary benefits. The University will pay first-class fares for the appointee and his family, and the costs of removal of furniture and effects. The University will also provide assistance in housing.

Further information about the position may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London, W.C.1.

Applications close on July 15, 1970. (1665)

UNIVERSITY OF LEEDS

TECHNICIAN

required by the Department of Experimental Pathology and Cancer Research to assist in the Electron Microscopy Section. A knowledge of electron microscopy techniques and photography would be an advantage but instruction will be given. Salary according to age, qualifications and experience on the scale £773 to £1,077 a year.

Applications, giving full details, including qualifications, in writing, to Professor E. H. Cooper, Department of Experimental Pathology and Cancer Research, The University, Leeds LS2 9JT. (1674)

UNIVERSITY OF READING

DEPARTMENT OF GEOLOGY

TECHNICIAN OR JUNIOR TECHNICIAN

required for electron-microprobe analysis. Experience in the following an advantage: (a) use and maintenance of X-ray equipment and/or electronic instruments, (b) preparation of metallurgical or geological materials for microscopy. Salary in the range £352 to £1,077 depending on age and experience.

Applications, in writing, to Assistant Bursar (Personnel), University of Reading, RG6 2AH, quoting T.16 by May 15. (1649)

Only four control —but what performance!

Simple to look at . . . just as simple to use. The new Unicam SP1000 Infrared Spectrophotometer.

Give your new lab technician a few minute instruction, and you have an immediate capacity for infrared spectra of the highest quality. You might think, because of all tha simplicity, that we have sacrificed somethi along the way. Just one thing—the price. Everything else is comparable to instrumen costing very much more.

How is this possible? For one thing we ha introduced a high performance Ebert gratin monochromator which gives excellent resolution. Then there is an improved pneumatic detector incorporating solid-sta circuitry, and a large (20 cm x 48 cm) inte strip chart recorder for supremely clear results. A full range spectrum (625-3800 cr will take you just two minutes, or for work the highest precision press the "slow scan button and wait less than five and a half minutes.

It will certainly pay you to learn more abou the SP1000. Or if your needs are even mor demanding then there is the Unicam SP12 Write or 'phone today for a free brochure.

What Future for American Universities?

THE past few weeks have caused many sober people to question the continued viability of universities in the United States. The shooting of four students at Kent State University, Ohio, two weeks ago is only one of the more dramatic signs of crisis. For the past two years, the cross currents within the academic system which have progressively complicated and impeded the process of teaching have been plain for all to see. It has nevertheless been a great surprise to see how trouble on the campus has spread from places such as Berkeley to universities such as Yale which quite recently were sneered at by the radicals for their primness and to universities such as Kent State, which until recently were remarkable only for their size. But student protests are only one symptom of underlying malaise. Over the years, and particularly this year, the extent to which scholars are supported in their research by the Federal Government has declined, so that there is a bleak prospect that the newer institutions in the United States will never graduate to the first division of academic institutions. Then there is confusion about the fitness of the curriculum for the modern world, and it has rarely helped as much as some academics hoped that several universities have bent their principles to accommodate the demands of students for instruction in this or that. But the universities are also under fierce economic pressure, and the past few weeks have been filled with announcements of higher fees for tuition in the coming academic year and with the gloomy prospect that several worthy institutions will in future be compelled to economize in the quality of what they do for students.

Where will all this lead? Although the pressures with which the university system is now confronted could probably be traced by a sufficiently energetic sociologist to some common cause, possibly a permanent change in the character of American society, universities must live from day to day and there is probably some benefit in seeking to disentangle the threads of the present crisis. The increasing involvement of the student body at many universities, and the faculty as well at many of them, has been in many ways the biggest surprise. A decade ago, after all, American universities were outstanding for their hard-working dedication to the accumulation of academic credit and for their indifference to what was happening outside. To be sure, Dr Nathan Pusey, president of Harvard, was one of several people who stood up to Senator J. McCarthy in the middle fifties, which is why it is so ironic that he should have been, with some justice, the target for much of the invective against university administrations in the past few months. (Harvard is now in the throes of choosing a new president for itself, and it will be interesting to see whether the high hopes now entertained that some kind of messiah will emerge from the selection process turn sour when, almost inevitably, they are disappointed.) At the beginning, even the Vietnam war did not set the campuses alight. Social issues, especially the racial problems of the United States, seemed among the first to draw American students into political activity. Senator Eugene McCarthy's attempt to win the Democratic nomination in 1968 was a sign that organized students could have an external influence on political events. With the invasion of Cambodia, there is no prospect that they will be ready to overlook the opportunities which now exist.

That university people should be engaged with political events is in principle entirely proper. Indeed, there is something in the old complaint that universities in the English-speaking world have traditionally been too indifferent to what goes on about them. It is, however, essential that everybody concerned should recognize that it is bound to be a gross interference with academic and even personal liberty to attempt to create situations in which individual universities can speak with one voice. In other words, if a faculty meeting or a student union meeting wishes to pass political resolutions and draw these to public attention, well and good. But it is not feasible to ask that universities in their corporate incarnations should take political positions—that would imply the suppression of disagreement within the universities, which would itself be an intolerable misinterpretation of what a university is for. To be sure, a lot of clamour within a university on some public issue can give outsiders the impression that universities as such are committed to the same view, but this interpretation is mistaken and should be described as such by any academic whenever the chance arises. One of the least pleasing features of the recent wave of protest from students and academics is that there have been signs of attempts to persuade the reluctant to put their names to petitions in which they do not trust, or to lend their presence for causes they do not share. It follows from this that if some sections of the university are proposing to exercise their legitimate right to engage in external political activities, it is unavoidable that all who work in the universities will sooner or later be drawn into a more direct concern with political events, if only so that they know as individuals where they stand. In the long run, if handled wisely, this development could be beneficial. After all, informed debate on political issues within universities could help enormously to clarify the public mind. One of the defects of the universities in the past few months is that those who have no wish to join the picket lines have been too passive. The invasion of Cambodia may be indefensible, but it has not been in the public interest that the universities have provided a great many of the more hot-headed leaders for what they call the battle to preserve the environment without there being any measured protest within the universities that a good cause may be being spoilt by exaggeration.

So does it follow that the universities can influence political events only to the extent that individual academics and students may have time and energy for political activities, and to the extent that their disputes with each other may be educative for the world at large? Evidently there is more to be done than this. For one thing, academics are usually more able than other people to make their views heard—they have the words and often the time. Plainly Mr Kingman Brewster, the president of Yale, has had a marked influence with his declaration in April that black revolutionaries could not easily find a fair trial in the United States, and by his help with student protest at Yale on May 1 against the treatment of Black Panthers. Similarly, the students—possibly 100,000 of them—who congregated outside the White House in Washington last weekend have clearly forced the government to acknowledge that they have a case—conceivably, they would have been even more influential if they had avoided mixing up with the issue of Cambodia all kinds of other worthy but irrelevant causes—the Black Panthers and Women's Liberation, for example. To be sure, there are dangers. The rough handling of a group of student activists by building workers in New York last week shows that the fondness of university students for the cause of what they call the working class is not always reciprocated, and there is a serious danger that the rival of political interest and energy in the universities may run into the sand by being too isolated from reality. In the long run, that could be damaging for the institution of the university. No doubt the building workers in New York last week were fully aware that the taxes which they pay are necessary to keep the universities alive.

Externally, then, the universities should not be afraid of being dragged into politics but should find ways of allowing this to happen without damaging academic freedom or the reputation of the universities for good sense. Perhaps the most valuable model is that devised at Princeton, where the university now plans to close for two weeks before the election next November so that students and faculty can do more to influence local politics. Internally, too, universities need to be more courageous. In retrospect, the demand of students to be involved with the administration of American universities has in the past been acceded to unnecessarily. It is, of course, right that students should have more say in the conduct of their own lives, but it is not sensible that they should have a direct influence in the planning of the curriculum. To be sure, there is plenty of room in every university for arguing about what is taught and how, but it is hard to accept the good sense of the arrangements made in some universities for teaching subjects which are hardly academic disciplines in an independent sense. The departments of black studies in several American universities have become relics of the period a few years ago when this cause came at the top of the revolutionary list. Over the years, the universities have been grudging in their response to the legitimate demands of students and weaker than they should have been in their resistance to unreasonable demands. The truth is, of course, that there is a difference of principle between the interests of students and of faculty; teachers are paid to teach what they can teach and students elect to listen to them. None of this justifies complacency about the present curriculum, but it would be as well if the present mood towards more vigorous discussion of external issues were also accompanied by a determination, principally by the faculty, to strike the right balance within the administration of the universities as well.

The external pressures to which universities are subjected is another serious cause for anxiety. Everybody knows by now that the upheaval in the universities has not made conspicuous friends among the taxpayers. Congress is equally inclined to listen to jaundiced views. And in any case, there are huge structural problems in trying to match financial support for university education with the common and reasonable assumption that higher education is something which everybody deserves. Already there are alarming signs that universities which are dependent on state governments for their financial support are being looked over with uncomfortable care by the boards of regents, so that many academics fear that it cannot be long before appointments are determined in the state house. Certainly there has been a marked disinclination already for state governments to help with the financing of university research—an activity which in happier times was regarded as a feather in the cap by the regents of the University of California. A part of the trouble may be that the comparatively recent invention of bureaux of the budget by the state governments has not yet had time to settle down. More probably, however, parsimony and petty interference have come to stay.

This is why it is important that the sense of unity within universities which seems to have been engendered by the external crisis should be used not merely as a way of persuading the American army out of Cambodia but also as an incentive to find a common defence of the university system against the pressures which are undermining it, externally and internally alike. In the long run, some better way has to be found for letting students and faculty coexist. The problem is to let students feel free and to permit faculty members to remain scholars. Nobody should sneer if it turns out that the external crisis which has caused the students to go marching serves also as a spur for putting the university system in order.

From Gentleman to Player

WHATEVER future is decreed for the Family Planning Association by the negotiations now in progress with the Department of Health and Social Security, it is no mean triumph that the government has finally acknowledged an active responsibility in this area. Concern about the growth of Britain's population, which may in part have prompted this change of heart, is an entirely separate and on the whole less pressing issue than that of providing all who need it with genuine access to modern methods of contraception. At present that access is denied, as the abortion rates alone will testify. But this is not to detract from the major expansion that the Family Planning Association has undergone in the last five years. It has doubled the number of clinics and raised to more than half a million the number of people who seek advice from them each year. The expansion has, of course, been helped by the 1967 Family Planning Act which empowered, but did not compel, local authorities to provide contraceptive services to all who required them, regardless of marital status. But the Association has had an uphill task to take advantage of this long overdue legislative support—according to a recent survey, only a quarter of the local authorities are now providing the full services recommended by the act.

The recent expansion has hastened the transition of the Family Planning Association from voluntary to professional status. The days of the great pioneers and of wrestling with the prejudices of the medical profession are ending, though not yet over. But now that the battle for public support has been largely won, the Family Planning Association is divided as to what its next goal should be. It is natural that differences of opinion should arise between those who see the major task of the Association as being to dispense contraceptive advice to the maximum number of people and others, particularly the medical staff, who wish to give consultation on sexual problems to a smaller number of people.

These differences may have been responsible for the recent resignation of Dr Hilary Hill, the deputy director (medical), which seems to have hastened the Association's plans for reviewing the medical side of its activities. A commission under Lord Platt has now recommended that the Association appoint a chief medical officer who would be backed by a smaller and more active panel of advisers than the present medical council. These proposals, which have been accepted by the national executive committee of the Association, reflect the growing technicalities of contraceptive practice and the need for the Association to provide authoritative medical opinions on advances in reproductive technology as well as on occasions when government committees or newspapers provoke unnecessary despondency about the pill.

The side-effects of the pill that are now reaching statistical significance have produced several kinds of headache for family planning administrators. There is not just the flight from the pill that alarmist pronouncements engender. The proliferation of medical tests which doctors like to give before prescribing the pill may reassure some women but inhibits others, particularly those who are liable to be intimidated by the clinical procedures. Unfortunately it seems that the latter category includes the type of women who stand most in need of family planning advice. This is one of the questions that is to be studied by the major survey of family planning services that is to be mounted shortly by the Department of Health and Social Security. The future status of the Family Planning Association may well be affected by the negotiations now under way, but even if in the name of integration the Association disappears into the arms of the health service, there could be no more significant tribute to the way in which it has tackled responsibilities which governments have shirked for so long.

100 Years Ago

The Royal Society

I CANNOT but think that the list of candidates recommended by the Council for election into the Royal Society published in your last number will be read by the outside world with considerable surprise. I look in vain in it for the names of two men, at least, of world-wide reputation, and well known as no mere *dilettanti* in their respective sciences, who were among the candidates, while the names of others are found there, which are on everybody's lips with the thought, What have they done to merit the scientific distinction which is looked on by every lover of science as almost an opening of the gates of paradise? Is it possible for us outsiders to learn anything of the considerations which govern the election? NOT AN F.R.S.

THE *British Medical Journal* states that the chair of Physiology, in the University of Prague, vacant by the death of the celebrated Purkinje, has been filled by the appointment of Dr. Hering, of Vienna. It was offered to Professor Helmholtz, who, however, preferred to remain at Heidelberg.

A RECENT number (94) of the German series known as "A Collection of Popular Scientific Treatises, edited by R. Virchow and Fr. von Holtzendorff," is a lecture on the Glacial Period (*Die Eiszeit der Erde*), by Alexander Braun. It gives a clear and concise history of the observations and arguments by which geologists have been led to the conclusion that a lengthened period of extreme cold overspread the greater part of Europe before the commencement of the historical epoch.

From Nature, 2, 48 and 51, May 19, 1870.

OLD WORLD

DEFENCE

Whittled Down Planes

THE decision to go ahead with the next step in the project to build what is known as the Multi-Role Combat Aircraft is now expected to be delayed for three or four weeks. The previous stage of project definition was completed at the end of February, and the agreement to begin the development stage, now involving the construction of seven prototypes to be followed by six preproduction aircraft, was to have been signed on May 1. But last month's announcement of a change in the requirements of West Germany, which is a partner in the project with Britain and Italy, appears to have reopened discussions of the basis on which the project is to be carried out. Meanwhile in Britain there is some unease about the project; the aircraft is the natural successor to the TSR-2 cancelled in 1965, memory of which still rankles. In particular there is a certain measure of public sensitivity about the series of cancellations of military aerospace projects which between 1951 and July 1967 are said to have cost more than £430 million. Recent remarks which the West German Minister of Defence, Mr Helmut Schmidt, is reported to have made in Bonn last week, which are thought to imply that the German requirements for the MRCA might be altered again, have not added to confidence in the project.

As the project stands at present the expectation is that Britain and West Germany will each take 400 of the aircraft, the design of which has not yet been made public, and Italy is to take 100. These figures represent a considerable whittling down of the original estimates which at one time had 600 aircraft on order for West Germany and 200 for Italy, although the British requirement seems to have risen slightly from 385 to 400. West Germany announced last month not only a reduction in its order but also a decision to take only the two-seat version instead of the mixture of single-seat and two-seat aircraft which were to make up the original 600.

Because of the alteration in the German position, the launching of the development phase has had to be postponed. The situation is complicated by uncertainty about the attitude of the junior partner, Italy, which after the German decision was the only member still wanting the single-seat version of the MRCA. The Italians have now also decided not to order the single-seat version, but their views on the two-seater are not known. It is considered possible but not likely that Italy may wish to drop out of the project altogether.

Confidence in the project has been further shaken by Mr Schmidt's recent pronouncement in which he apparently succeeded in implying that the German requirement for the MRCA may be reduced yet again. This was read into a statement that the ill-fated Starfighters of the West German Air Force are to continue in service longer than expected, to the end of the seventies, and that the German requirement for the MRCA would be 420 at most. The original plan was for the MRCA to replace the Starfighter in the German Air Force. Meanwhile in the House of Commons the British Minister of Defence, Mr Denis Healey, has been parrying questions about the cost of the project which, before the decision to proceed only with the two-seat version, was thought to be a total of about £470 million for the research and development work. On top of this is the unit cost for each aircraft, believed to be about £1·86 million for the two-seat version.

RESEARCH COUNCILS

Giving to Him who Hath

THE Science Research Council faces the permanent dilemma of whether to concentrate its support on a few centres of excellence or to spread its resources thinly among all the possible claimants, few of whom may achieve excellence in any field. The former strategy leads to charges of favouritism; the latter would threaten the quality of the national research effort. Moreover, the government expects that at least some of the £100 million entrusted yearly to the SRC will be devoted towards national goals, however ill-defined these may be.

What then is to be done? According to Sir Brian Flowers, chairman of the SRC, the best policy is to steer a middle course but at the same time to lean heavily towards a few institutions where expertise has been built up and where the resources will be used to their best advantage. Sir Brian, who was addressing the industrial committee of the Science of Science Foundation last week, lamented the way in which economic crises and mounting disillusionment with science have cut the rate of growth of science budgets to inadequate levels and forced an even greater measure of selectivity on the SRC.

About a quarter of the SRC's grant is spent in areas which the council wishes particularly to stimulate, such as astronomy and computers, while the rest goes on grants for individual projects. Applications for money should be judged by five criteria, Sir Brian said. Will the project contribute to the internal well-being of that particular subject? Will it help other branches of science? What are the economic, social and cultural implications of the project? It is inevitable that the largest slices of the SRC's cake go to institutions which have built up centres of excellence in particular fields so that in the course of time resources become more and more concentrated with the strong universities becoming stronger and the weak, in relative terms, weaker.

The Social Science Research Council does not have the same problems because the type of research it supports does not require large capital expenditures and there is no similar pressure to concentrate its resources. Mr Andrew Shonfield, the chairman of the SSRC, pointed out at the same meeting the problems in assessing the possible significance of a social science research project. Many of the social sciences are in a formative stage of their development and, according to Mr Shonfield, the best that can be expected from social science research in any case is that it "might be able to develop a few social indicators which tell us where we are now". It is therefore unrealistic to support social science research for its practical possibilities alone and the SSRC should be guided by other criteria as well. One of the council's aims is to encourage team work, especially interdisciplinary team work, but this policy runs up against the problem that most social science research workers wish to be heroes in their own right, and are less ready to collaborate than are natural scientists. There is also the problem, Mr Shonfield said, that some social scientists believe that interdisciplinary work taints them.

COMPUTER POLICY

ICL's Feather Bed

THE final public session this week of the investigation of the British computer industry which is being carried out by a subcommittee of the House of Commons Select Committee on Science and Technology has revealed the extent to which the major British manufacturer of hardware, International Computers Limited, is favoured by government orders. ICL received 99 per cent by value of central government orders for administration and general purpose computers placed in the year ending March 31, 1969. But the situation was less favourable for ICL during the last financial year, when its share of orders fell to 67 per cent.

These figures were given to the subcommittee in a memorandum from the Civil Service Department, which defines its role in the computer field as the central coordinator which ensures that government policy on the use of computers within departments is correctly applied. During the remainder of 1970, according to the memorandum, the government expects to order £20 million worth of computers of which ICL may supply up to 80 per cent.

Leading the team from the Civil Service Department and from the Stationery Office, which deals with the mechanics of the purchasing process, was the deputy secretary of the Civil Service Department, Mr N. G. Morrison, who gave the clearest definition of the rules applying to the choice of computers for government use that the subcommittee has heard. With two important exceptions, the process is to seek competitive tenders from three firms including one which offers equipment manufactured in Britain. The contract is awarded on merit, but there is a preference in favour of British machines provided there is no undue price differential. But Mr Morrison refused to specify in public session the size of the allowed price differential, alleged by Mr E. Nixon of IBM (UK) to be 25 per cent, although in an earlier session Sir John Wall, chairman of ICL, denied any knowledge of a preference favouring ICI.

The exceptions to the rule are computers more powerful than Atlas which are acquired from ICL without requesting tenders from other manufacturers, subject to the conditions of satisfactory price, performance and delivery dates. This applies to machines such as the ICL 1906A and System 4-70. Smaller computers are also acquired by requesting only one tender, usually from ICL, when they are intended to precede the use of larger machines from the same family or where there are other reasons for buying a particular machine such as compatibility, again subject to price, performance and delivery.

The policy of single tendering has of course been worrying the subcommittee and the extent to which ICL has benefited was given in the Civil Service Department memorandum (see Table). Mr Ted Leadbitter of the subcommittee, for example, wondered how the decision on single tenders could be subject to price, performance and delivery date when no other manufacturer had been consulted. But the witnesses thought that single tendering was the most efficient way of obtaining large systems.

CENTRAL GOVERNMENT ORDERS FOR COMPUTERS

	Value of all orders with all manufacturers £1,000	Value of all orders with ICL £1,000	Value of single tender orders with ICL £1,000
Orders placed (April 1, 1968, to March 31, 1969)			
Administration and general purpose	7,590	7,490	4,440
Scientific purposes	2,225	1,720	
Orders placed (April 1, 1969, to March 31, 1970)			
Administration and general purpose	13,025	8,780	8,350
Scientific purposes	4,260	325	75
Total	27,100	18,315	12,865

How the mechanism of the procurement of computers for use in government departments might be simplified from the present system, which apparently involves the Civil Service Department, the Stationery Office, the Treasury, and the Ministry of Technology in addition to the department which is receiving the computer, is also being discussed by the subcommittee. To the suggestion that the part played by the Stationery Office is taken over by the CSD, Mr Morrison said that the CSD has no experience of ordering and he doubted whether anything would be achieved by transferring staff from the Stationery Office to do the job. Mr Leadbitter thought that a lot of woolliness would vanish if the CSD and the Stationery Office were removed from the scene and the evaluation of tenders and procurement were done by the user department. But the witnesses felt it important to have a central coordinating body such as the Management Services Division of the CSD which deals with computer affairs.

The interrogation of Mr Morrison and his colleagues marked the end of the public sessions of the examination of the prospects for the British computer industry which has been occupying the subcommittee since February. Computer manufacturers, the software industry, large users of computers and the Ministry of Technology have given evidence to the subcommittee, which has become noted for its thoroughness. The subcommittee's report is expected to be available by July.

ASTRONOMY

Sic Transit Gloria Mercurii

FULL honours were done at the Royal Greenwich Observatory last Saturday to the transit of Mercury across the Sun's disk. On the lawn of the observatory a forest of antique telescopes was pointed defiantly through the blanket of clouds at the putative position of the Sun. An enthusiastic group of observers who had been manning their instruments since the beginning of the transit at 4 a.m. stood around like so many stout Cortezes, waiting for a break in the clouds and the planet to swim into their ken. The purpose of the occasion was to celebrate the transits of Venus and Mercury observed by Captain Cook 200 years ago, the former from Tahiti, which was the original purpose of his voyage to the southern hemisphere, and the latter from Mercury Bay, New Zealand. It was after this observation that he charted New Zealand and discovered the west coast of Australia.

The reason for sending Cook to observe the transits of Venus and Mercury from the southern hemisphere was to measure the planets' parallaxes, which at that time offered the best hope of calculating the mean distance between the Earth and Sun. The occasion was also notable for being the first really international scientific event—altogether some 150 observations of the transit of Venus were made from twenty-five countries under the aegis of the Royal Society and Nevil Maskelyne, the Astronomer Royal of those days.

Last week's observations, in which two of the telescopes were identical to those used by Captain Cook, were in part a nostalgic exercise in memory of the days when Greenwich ruled the heavens—the Greenwich meridian passes by a few yards away—and in part, no doubt, a cunning allusion to the present scandalous discrepancy between the radar and astronomical estimates of the Earth–Sun distance that Captain Cook was sent south to measure once and for all. But whether in nostalgia or satire, the clouds above Greenwich finally thinned to reveal a watery Sun, glinting down on the Dolland and Sheepshank telescopes, the Altazimuth dome, the orreries, astrolabes and armillary spheres of Greenwich. The observers hastened to their tripods, lead weights were re-hung, clockwork drives creaked into action and the image of the Sun's disk came into focus in a dozen eyepieces. There was Mercury, making a fine transit right across the middle of the disk, threading its way through a veritable rash of what the observers said were sunspots but which may have had something to do with the specks of dust on the antique object glasses.

ENGINEERING

Shaping up Ship Research

The establishment of a unified Shipping Research and Development Institute and a separate industrial training board for shipping are among the chief recommendations of a committee investigating the shipping industry in a report published last week (*Report of the Committee of Inquiry into Shipping*; HMSO, £3). The committee, set up under Lord Rochdale in 1967 by the President of the Board of Trade, emphasizes the shortage of good management in the middle echelons of the industry and comes out firmly against substantial state involvement in the industry. It rejects the need for any increase in government expenditure on research and development in shipping.

Although the report dwells for the most part on trade and manpower questions, the committee has clearly found cause to study in some depth the innovative side of the industry. For one thing, research on shipping and relevant aspects of engineering is unnaturally fragmented, the committee points out. There is no shortage of money for R and D projects—government expenditure compares favourably with that in other countries—but there is a lack of coordination within the industry, because companies are too preoccupied with safeguarding narrow commercial interests.

The establishment of a central R and D institute is the remedy proposed by the committee. The institute would embrace the Ship Division of the National Physical Laboratory, the British Shipping Research Association and the Shipowners' Refrigerated Cargo Research Association, with anyone else free to join should they wish. But despite the committee's designs it seems unlikely that the limited research of direct relevance to shipping being undertaken at places like the National Engineering Laboratory, East Kilbride, and the Hydraulics Research Station at Wallingford, will be transferred from the present sites.

The British Ship Research Association, founded in 1944 as a central research organization for the shipbuilding, marine engine and ship repairing industries, has, with government encouragement, extended its interests to include limited research on behalf of the shipowners. Of the £1·15 million research budget for 1968/9, the government contributed 34 per cent, the shipowners 7 per cent, and most of the remainder was provided by the shipbuilders. Only about a third of the £700,000 annual income of the NPL Ship Division comes from bodies other than the government. Apart from testing marine craft and ship propulsion devices the Ship Division also undertakes more fundamental research into ship hydrodynamics and propulsion and has recently increased its involvement in basic ship design.

The pattern of university research into shipping reflects academic demarcations between disciplines. Thus a project of computer aided ship design is being undertaken at Imperial College, London, under a contract from the Ministry of Technology. Naval architecture, however, derives its research funds from a range of different bodies, including the Science Research Council, the BSRA and the Institution of Naval Architects. The committee notes the little work being done at universities on engineering, equipment or systems specifically for ships, and chides the Chamber of Shipping for its lack of a university research programme. The shipowners together claim to spend about £3·6 million a year on R and D, but much of this could also be labelled production work. Only 4·7 per cent of this figure goes on automation and instrumentation and 3·5 per cent on hydrodynamics and basic ship design.

SCIENCE POLICY

Science No Longer an Opiate

In the rush to exploit the results of research and development for economic ends, social implications have often been overlooked and future developments in science are now greatly feared by an increasingly more vocal public. These fears have found expression in the growing hysteria about pollution, in demands for reductions in government support of scientific activities and even, in the United States, in a trend towards a general anti-intellectualism. This gloomy picture was painted last week by Dr Alexander King, Director-General for Scientific Affairs of the Organization for Economic Cooperation and Development, at a lecture given to the Science of Science Foundation. The remedy, he said, lies in a different approach towards the planning of science and technology. If the anti-scientific lobby should succeed in curbing the activities of science and technology, society would lose one of its most powerful weapons for solving social problems. But fundamental changes must be made in present thinking on science policy.

For one thing there must be a change of emphasis from an economic incentive for technological development to one in which the research effort becomes an instrument for improving the quality of life. This requires a high degree of cooperation between different disciplines and a herculean effort from the social sciences in particular, Dr King said. The first step, however, is to get away from the idea that economic growth is an end in itself, and to replace the index of gross national product with a measure which would include qualitative elements and data derived from social indicators. Such a shift in priorities would channel more attention to social problems as well as encouraging a clearer formulation of national goals.

Although the formulation of national goals is beyond the scope of science policy as such, Dr King suggested that the scientific approach has much to contribute through a dialogue which relates needs to new possibilities. In the lack of clearly defined national goals, science cannot redeploy its resources to meet the needs of society. But to do so requires a collective statesmanship on the part of scientists whereas too often scientists operate as separate and unnecessarily competitive pressure groups which may serve the interests of particular disciplines but are ineffectual if research is to contribute anything towards changing national objectives.

There is room for international cooperation, Dr King suggested, in assessing the social and cultural as well as the economic consequences of alternative technological developments. For example, a world wide early warning system on the environmental and social threats posed by new technological projects could help to avoid many of the disasters of present planning procedures which, Dr King suggested, "often serves merely to make situations which are inherently bad, more effectively bad".

It is in governmental and political structures, however, that many of the more fundamental changes are needed. The vertical organization that is found in most countries is unresponsive to the complex problems that confront science policy, and Dr King suggested that an integrated approach is difficult to achieve when a large number of government agencies are responsible each for a particular fraction of a major problem area. Establishing still more coordinating committees will not help. "Strategies concerning science, technology, economic and social policy must be considered in their interactions," he said, and this "would seem to require a senior minister, placed close to the prime minister but without departmental portfolio, to develop integrative and longer term policies."

MARINE EXPLORATION

Diving Saucers

SEA trials of the latest French deep diving vessel began last week off Marseilles. Built and equipped at a cost of some £375,000 to the Centre National d'Exploitation des Océans, and capable of descending to 3,000 m below the surface, the *soucoupe plongeante* (SP 3000) is one of a series of submersibles that stem from designs by Commander J.-Y. Cousteau's research group in the late 1950s. The French Navy is already interested in borrowing the vessel to photograph the remains of the submarine Eurydice which was wrecked a few months ago, and other possible uses include direct exploration of such places as the mid-Atlantic ridge as well as allowing marine biologists to plumb new depths.

Despite its name, the SP 3000 has the shape of a rugby ball. A tough fibreglass shell encloses the engine, the steering equipment and the central cabin, which is a steel sphere with room for three people; three batteries provide the power and the vessel can travel at up to 7·5 km/h, although, unlike the earlier SP 350 which propelled itself by ejecting jets of water under pressure, the SP 3000 is driven by twin screws. During its trials it is based on the oceanographic ship Jean Charcot, which seems at present to be the only ship with the facilities for launching it at sea. Plans for expanding the fleet of the Centre National d'Exploitation des Océans provide for building several smaller ships that will be able to use the SP 3000.

TECHNICAL COLLEGES

Stretching the Year

by our Education Correspondent

TECHNICAL colleges in Britain have been categorically included in the effort to improve cost effectiveness in educational establishments. In a closely argued report, the Committee on the More Effective Use of Technical College Resources has urged local education authorities to take a hard look at the colleges under their control to see what profit there may be in increasing the length of the college year. (*A Report of an Inquiry into the Pattern and Organization of the College Year*, HMSO, 3·5*s*.) The committee, which advises the Secretary of State for Education and Science, is careful to say that its recommendations must be interpreted according to the needs of each individual institution, but it comes down firmly in favour of lengthening the college year on the grounds of more efficient use of resources. This should allow new types of course to be taught, and will fit in better with the requirements of industry.

Although there has been a trend in recent years towards keeping colleges open for 48 weeks a year instead of the traditional 36 or 37, the committee points out that only a few students are taught during the extra weeks, and that very few colleges have rearranged their courses to gain the maximum benefit from the extra opening hours. For example, there is still considerable scope for running the same block release course several times a year so that it can be taken at the appropriate point in a student's industrial training, and there is no reason why the length of the year for part time students should be the same as that for full time students. A lengthening of the year for part time students, the committee suggests, could be used to broaden the content of courses, and it will also even out the load on a firm's training facilities.

The further education sector is, of course, more able to incorporate changes of this kind because of the diversity of courses which its establishments provide, but similar arguments are gaining some ground in the higher education sector as well. The government has already canvassed the possibility of introducing four term years in the universities, and it is still casting around for ways to meet the demand for places in higher education as cheaply as possible. But—

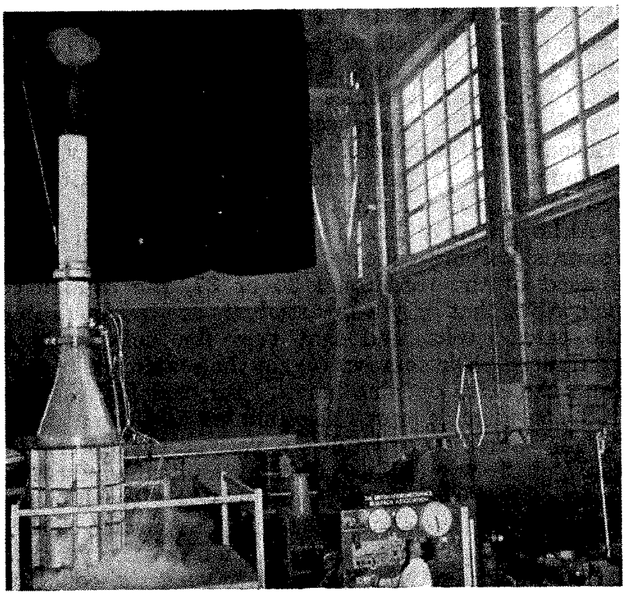
elections permitting—the education world should know in the next three or four weeks what is in store for it when the government publishes its long awaited green paper on education.

POLLUTION

Vortical Chimneys

Chimneys that blow smoke rings are not just a Dadaist's dream. A model which does just this has been built by a team under Dr P. J. Baker in the laboratories of the British Hydromechanics Research Association at Cranfield, near Bedford. Cheaper in principle than the tall chimneys that are at present used to discharge industrial smoke, the design uses a fluidic switching system to punch out smoke in discrete vortices.

The advantage of a vortex is that it can roll upwards instead of sliding through the air as a plume of smoke does and, because the friction is reduced, the smoke can ascend perhaps four times as high. Although the idea is not new it has been hard to devise machinery for generating the vortices that does not require heavy maintenance. The fluidic valve developed by Dr Baker's team diverts the smoke into a ring-shaped reservoir between puffs. A blast of high pressure air, introduced by a vertical pipe that rises through the centre of the chimney, draws the smoke out of the reservoir and with the help of the internal geometry of the chimney imparts to it a rolling motion. After the smoke ring has been expelled, a mechanical valve at the top of the chimney cuts off the smoke that remains inside and sends it back to the reservoir.



General view of model emitting smoke ring.

In the laboratory the rings last for some while, but it is not clear how they would fare in a stiff breeze. In theory their stability should depend on the ratio of the ejection speed to the wind speed, and a shield at the top of the chimney might allow rings to form fully before they are released. One teething trouble is that each puff produced by the model sounds like a blow from a steam-hammer but the use of absorbent materials should solve the problem.

The next step is to construct a larger model for testing in the open air, after which an industrialist sponsor will be needed to support a full scale trial (the National Research Development Corporation is backing the present work). The most useful habitat for the fluidic chimney is expected to be in valleys and densely populated areas where smoke near the ground is a particular nuisance.

HYDROGRAPHY

Floating Superproblems

The new breed of supertankers of over 200,000 tons, and the prospect of even larger ships up to 500,000 tons in the future, is creating a major problem for hydrographers, according to the annual report by the Hydrographer of the Navy, Rear Admiral G. S. Ritchie. Many of these vessels have draughts of more than 80 feet and there is an urgent need for detailed surveys of routes that are suitable for them. In particular, the report expresses anxiety about the minimum clearances which are accepted by the tanker companies.

The problem is that the sort of surveys which are required to make the operation of these vessels safer take time to complete and are expensive. "In the meantime," the reports says, "the construction of these monsters continues." In particular Rear Admiral Ritchie is concerned in his report about the risk to deep-draught vessels around north-west Europe. The seas in this crowded area are shallow and changeable, and cluttered with the wrecks of two world wars. To make matters worse, there is apparently a tendency to allow supertankers to be used in critical navigational conditions so as to get the most use out of expensive capital assets.

This is why Rear Admiral Ritchie says it is important to chart the deep water approaches to the British Isles, in particular the southern North Sea westwards of 3° E, which delineates the approaches to the Thames Estuary and the English Channel. The same applies to the Persian Gulf and the Malacca Strait between the Malayan Peninsula and Sumatra, all on important tanker routes. An additional hazard which crops up in the North Sea and the Malacca Strait is the presence of what are called sand waves which often shift their positions and can be up to 30 feet in amplitude. This is a problem which the Natural Environment Research Council is investigating.

Rear Admiral Ritchie points out that the charting of the Persian Gulf and of the North Sea is a British responsibility. An international effort involving Britain, Japan, Indonesia, Malaysia and Singapore is dealing with the Malacca Strait.

EXHIBITIONS

Peering into the Micro Era

The international Instruments, Electronics and Automation Exhibition that opened at Olympia last week was billed as the largest exhibition of its kind ever to be held in Britain. Certainly a varied collection of genuine innovations was on display, together with instruments the style of which was not always perceptibly different from those of earlier years.

Automatic Systems Laboratories displayed a high precision thermometer capable of measuring to better than one millionth of a degree at 1 K, a device developed in conjunction with the National Research Development Corporation. EMI took the occasion to promote its impressive array of electron microscopes and microanalysers, and Thorn Colour Tubes Ltd set the seal on the colour television era by advertising its intention of manufacturing more than 300,000 colour television sets a year from 1971 at its new factory in Lancashire.

An interesting exhibit in nuclear engineering was an automatic beta gamma spectrometer, made by Nuclear Enterprises Ltd, with facilities for liquid scintillation and gamma counting and an automatic sample changer. Another attraction was the Computer Technology's "fun palace", in which visitors were invited to pitch their gaming skill at one of Computer Technology's new modular computers.

One exhibit with special appeal was the S-band power amplifier which was used to boost the television, voice and telemetry signals from the Moon. An important feature is the redundancy built into the equipment to guard against the failure of any component.

PESTICIDES

DDT Safe but Resistible

In the last few months resistance to insecticides has been growing almost faster among people than insects and the usefulness of the chemicals is becoming seriously eroded. As far as biological resistance is concerned, a hundred species of insect have become immune to DDT between 1962 and 1968, compared with the 81 species that developed resistance in the previous six-year period, according to a report compiled by the World Health Organization's Expert Committee on Insecticides (*Insecticide Resistance and Vector Control*, WHO, Geneva 1970. £1·25; $4).

According to a questionnaire sent to public health authorities throughout the world, the insecticides that are chiefly used in the control of disease carriers are the organochlorines DDT, HCH and dieldrin. But a growing number of insect species have developed resistance to one or more of these chemicals. In many places resistance has been acquired by the principal malaria vectors, and in West Africa DDT and dieldrin are essentially useless.

On the effect of DDT in the environment the WHO committee seems to have shifted its ground a little from its statement in 1967 that "the safety record of DDT remains outstanding . . .; the concern . . . about contamination of the environment by this very stable and persistent insecticide should not . . . be considered sufficient reason for substituting other insecticides". Rather more concern is shown now, but although the committee recognizes the desirability of using less persistent compounds it still feels that DDT must continue for some time yet to be a major insecticide.

The present concern about environmental contamination has led to restrictions on their use and to support for more biologically orientated research. Genetic control has received much of this attention and encouraging results have been achieved with sterile male techniques including those based on naturally occurring sterility mechanisms such as cytoplasmic incompatibility and hybrid sterility. The latter uses hybrid crosses which produce males which are sterile but show increased competitive mating ability because of hybrid vigour.

But although the use of chemical insecticides on an empirical basis is beginning to give way to biological techniques based on a more fundamental understanding of insect biology, the committee emphasizes that control must continue to rely on chemical pesticides for the control of insect and rodent vectors of disease; its opinion is that it is not realistic to expect that alternative methods will become available in the near future.

CHEMISTRY

Forced Changes

An investigation into the way that chemistry is taught in British universities is to be conducted at the University of Liverpool. The university has been given a grant of £7,000 for the study by the Leverhulme Foundation, and it is expected to take about three years to complete. The main incentive for the investigation, it seems, is that universities are finding that they have to adapt more and more to changing patterns of teaching in the sixth forms, and the pressure for change at university level will become even more acute if the proposals for "Q" and "F" level examinations are accepted in July by the Schools Council and the Standing Committee on University Entrance.

Professor A. K. Holliday of the Department of Physical Chemistry at Liverpool and Dr W. J. Hughes of the School of Education, who will jointly supervise the investigation, believe that by 1972 most students entering university to read chemistry will have a very different educational background from present entrants. Acceptance of the Nuffield sixth form science courses and the more liberal A level syllabuses being introduced by some examining boards—especially London and the Northern Universities Joint Matriculation Board—means that many will not have read chemistry as a separate subject and their knowledge of the basic facts will be less firmly grounded although they should be better acquainted with the important principles. Moreover, students who have taken the carefully planned new school curricula will expect their university courses to be equally well thought out.

The investigation will be concerned in the long term with the effectiveness of the whole teaching system, including lectures, tutorials, laboratory work and the assessment system. In the short term, it will look at changes in laboratory courses. The study is claimed to be the first of its type, which is surprising because it deals with the kind of problems facing every chemistry department. But fortunately one of the conditions imposed by the Leverhulme Trust is that the results of the investigation must be made freely available.

The proposals for Q and F level examinations and the accompanying changes in sixth form curriculum which would call for even greater changes in the universities now seem to be running into mounting opposition. A group of Leicestershire teachers have started a movement aimed at persuading the Schools Council and the standing committee on university entrance to reject the proposals when they come up for acceptance in July. The main complaint is that the proposals could lead to three examinations in three years, and that they will not necessarily broaden sixth form curriculum.

Parliament in Britain

Defence Research Contracts

THE Ministry of Technology expects to spend about £1 million during 1970–71 on university agreements sponsored by its research and development establishments. About £250,000 of this will be spent on wholly civil projects for the industrial research establishments, and the rest, which relates to agreements sponsored by the aerospace establishments, consists chiefly of research which has both civil and defence applications. Dr Ernest Davies, Joint Parliamentary Secretary, Ministry of Technology, who gave this information in reply to a question from Mr James Dickens, said that it is not yet possible to say how the total amount will be apportioned between the various universities.

Pollution of Scottish Waters

ABOUT half of Scotland's effluents are discharged into the Firth of Clyde, and about a quarter into the Firth of Forth. There is pollution on the West Coast from iron and steel manufacture, from coal, sewage sludge, paper pulp, sugar refining, power station wastes and from the dumping of explosives and sometimes of explosive wastes. This dismal picture was painted by Dr Dickson Mabson, Minister of State, Scottish Office, in reply to a debate initiated by Mr John Rankin, but Dr Mabson could give no assurances that fresh legislation would be brought in to deal with the situation. The Clyde River Board, he said, spends about £150,000 a year dealing with pollution of that river, and the white paper which was promised when the Royal Commission on Pollution was set up may lead to controls in areas where there is an obvious problem. (Debate, May 6.)

CS Gas

THE government has no intention of reconsidering its policy towards CS gas in the light of evidence from tests carried out by the United States Army. Mr Stewart said that he has examined the evidence carefully and that it contains nothing to upset the government's view that CS cannot be regarded as significantly harmful. The Foreign Secretary did not agree with Mr Frank Allaun that if Britain excludes CS from the Geneva Protocol, that may encourage other nations to remove their pet weapons from the ban. (Oral answers, May 4.)

University Salaries

THE government has given its approval to new machinery for negotiating the salaries of university teachers. The first stage of the negotiations is for the Association of University Teachers and the university authorities to agree on a claim, which would then be put to the government as the paymaster. There is also provision for arbitration if final agreement cannot be reached. Announcing the government's agreement to these proposals, which had been put forward by the Association of University Teachers, the University Grants Committee and the Committee of Vice Chancellors and Principals, Mr Gerald Fowler, Minister of State in the Department of Education and Science, said that the salaries of clinical staff will continue to be related to those of hospital doctors and dentists, and they will be determined by the government in the light of recommendations put forward by the Review Body on Doctors' and Dentists' Remuneration. The setting up of this machinery means that the university salaries will not come under the control of the Commission for Industry and Manpower. (Oral answers, May 7.)

Miscellaneous Intelligence

AN article in a recent issue of *Physical Review Letters* is entitled "High-momentum-transfer neutron-liquid-helium scattering Bose condensations". This equally-straining-to-mind-and-eye nearer-to-Teutonic-syntax-than-English demeaningly-tortuous-way-to-commune-with-even-one's-professional-colleagues stylistic solecism is one that can be taken too far.

THE Hydrographic Department of the Ministry of Defence has raised from 1*s* to £1 its minimum charge for answering public enquiries about wrecks, a 20-fold increase on which even treasure hunters may founder and the Prices and Incomes Board sink without trace.

DID any Romeo ever sigh beneath his Juliet's balcony and proclaim his "affiliative need, mutual absorption and desire to promote another's (*scilicet* Juliet's) welfare"? Even if not, that is what he meant to say, if the verdict of the American Association for the Advancement of Science is anything to go by. The AAAS has awarded its annual Socio-Psychological Prize to a sociological thesis on romantic love, love being defined in such terms for the purposes of the study. The purpose of the prize is "to encourage in social science research the development and application of dependable methodology on the lines of the natural sciences".

MANUFACTURERS of cyclamates in Britain and the United States may not have liked the ban on the artificial sweeteners imposed last year, but at least they lay down under it. Not so in Japan where the Kanto Chemical Sweetenings Industry Association and the East Japan Association of Producers of Artificial Sweetenings have sued the government for $500,000 to cover the losses incurred from the ban. The associations claim that the government studied only the research carried out in the United States and failed to collect data in Japan, whereas it is required by the food sanitation law to use the findings of research conducted at more than two places.

MRS CHERUBINA ALLIEGRO of Naples has attained the 108th year of her age, which she attributes to never having taken any medicine.

THOSE who complain that scientists, even physicists, write with too little confidence will be cast down by the following passage:

"We choose not to review each of the developments in detail here, but wish only to state that in our opinion no one of these authors has derived the most general and complete set of results that is achievable, nor has used as simple and self-contained a formalism as possible.

"In this paper we attempt to collect the results of the previous authors on the self-consistent phonon theory; to correct some minor errors; to extend the results to more general situations in several directions; to correlate these results by deriving them all from a single formalism; and to select a formalism for their statement which we feel is clearer and more compact than others, while no less powerful. The functional variation technique which we employ, while not entirely novel, at least has not been used previously in the study of lattice dynamics for which we feel it is ideally suited."

No prizes will be awarded for identifying the source.

NEW WORLD

Another Echo of Received Doctrine

THE most recent public complaint about the condition of basic science in the United States has popped up within the White House itself in the form of a report of a Task Force on Science Policy under Dr Ruben F. Mettler, president of TRW Inc. The committee was set up last October with a request from the Administration for guidance "for 1970 and beyond". In practice, although the task force has added its voice to those who plead for a stronger role for the National Science Foundation in the support of basic science, and although it takes up the long forgotten theme of the need that the Federal Government should acknowledge the support of graduate education to be a federal responsibility, its report will not help to distinguish between the more radical proposals for change put forward by other bodies.

The task force has tried to spell out the reasons why science and technology are important. It argues that vigorous programmes in science and technology are necessary in fields as different as national defence, arms control and the improvement of personal health. It shakes its head over "the rapid rise of attitudes disdainful of science and technology" and says that the solution is better public understanding of both the limitations and the promise of science and technology. The task force also considers that "leadership and excellence in science" should be, for the United States, an objective in its own right. There follows from this, the argument goes, a need to balance regional and national interests within the United States and also a need that scientific techniques should be used to predict the evolution of social problems and their solution. Above all, science and technology are essential for economic growth and the task force seeks to make this point by quoting Mr Kosygin's view, in March 1966, that the outcome of the competition between "the two world systems" would be determined by scientific development. What the task force asks is that the President should affirm in public that the development of science and "continuing leadership" in science are important national roles.

The task force argues that several things can be done to make better use of science and technology and to make these uses seem more relevant. This part of the report will no doubt bring comfort to the National Science Foundation, also now beating this drum (see *Nature*, **226**, 495; 1970). One field in which better use might be made of existing skills is in the development of health services—"we have failed to devote sufficient resources to defining the ways in which existing technology can improve health care and at the same time help control its cost". But the task force also asks that the social and behavioural sciences should be given more support and more scope for dealing with practical problems and suggests that there should be programmes of development towards "a system of social indicators", a national data system for use in the social and behavioural sciences, graduate schools of applied behavioural science and more money for research in these areas, long term and applied. The report suggests that the National Science Foundation and the Office of Science and Technology should between them take the initiative. It also pats on the back the several groups, from the Daddario committee and the National Academy of Sciences to the National Academy of Engineering, who have recently given the name "technology assessment" to the process of trying objectively to decide whether particular pieces of technology have a valuable role to play in the solution of social problems.

What this boils down to is the recommendation that departments of the Federal Government of any size should be asked to develop, and then to maintain, ten or fifteen year projections of their long term plans in such detail that the consequences can be anticipated by planners and scientists alike. As the task force sees it, the Office of Science and Technology should play the central role in coordinating these plans and trying to identify the points at which scientific and technical people could help to ameliorate the consequences of change.

The essence of the task force report lies in its recommendations on the machinery for supporting basic and applied research with federal money. The committee says that current problems have emerged only because expenditure has stagnated or even declined. Indeed, in the past four years, when the level of government support has remained for practical purposes constant, the committee estimates that inflation has decreased the real resources available by a quarter—a calculation which takes no account of the increasing cost of scientific research. But, the task force says, the universities are still turning out young people previously encouraged to work in science and who now find it hard to obtain jobs "consistent with their interests", while the mission agencies, under pressure from their own budget, have abandoned research in several areas of science—the Office of Naval Research has pulled out of nuclear physics, the Advanced Research Projects Agency has retrenched in material sciences, and the National Institutes of Health are no longer supporting chemistry and plant science on the old scale, so that the balance of American science has been distorted. The task force complains that the National Science Foundation is not in a position to take over projects abandoned by the mission agencies, that "mature and productive investigators in all disciplines" are finding it increasingly difficult to carry on their work and that universities are embarrassed because they cannot meet obligations sensibly assumed in times when money was easier to find.

What is to be done ? What the task force suggests is that "the time has come for more effective commitment to long range research" and that the National Science

Foundation should become the chief government agency for this work, with the National Institutes of Health following close behind. The task force says that the cost of supporting basic research will continue to increase with the national economy, and suggests that the budgets of the National Science Foundation and the National Institutes of Health should be tied to the Gross National Product. The argument is that increasing prosperity will bring proportionately increasing demands for improvement in urban planning, health care, education and the like.

Graduate education plays a central part. The task force says that there have been so many studies of this issue that the Federal Government should by now know enough to take effective action, and it commends the spirit of the first report of the National Science Board, which, at the beginning of 1969, asked for a federal commitment to graduate education and for a new pattern for distributing funds to universities based on a variety of novel types of grants to university departments as well as traditional grants for research projects. Lending further support to the wishes of organizations such as the Daddario committee and the National Science Board, the task force also asks for fuller use of federal laboratories and indeed goes as far as to say that the Federal Government should discourage "completely self-contained capabilities within mission oriented research institutions".

But how should these questions be coordinated? The task force asks for a more explicit concern for the comparatively small proportion of the federal budget for research and development which finds its way into basic research—a mere nine per cent of the $17,000 million a year at present being spent. The difficulty under the present arrangements, according to the committee, is that for lack of coordination within the Federal Government, decisions between different fields of science are being made without a balanced judgment of all the pros and cons. The task force asks that the Federal Council for Science and Technology should take responsibility for this kind of judgment, chiefly because this is the only instrument of the Federal Government likely to persuade the agencies to do what is expected of them.

In practical terms, the task force would like to see the budget of the National Science Foundation increased as rapidly as possible to 0·1 per cent of the Gross National Product. At this level, the National Science Foundation would be responsible for roughly one third of all basic and academic research supported by the Federal Government, but it goes on to say that several years may be needed to reach such a condition. The committee's report also wishes to see the National Science Board's report on graduate education turned into law not later than a year from now, a survey of the federal laboratories to see what better use might be made of them, and the confirmation of the Office of Science and Technology as the chief instrument for negotiating priorities in basic research.

The committee echoes several recent pronouncements on science policy by asking that there should be more research within the military programme "even at the expense of current military hardware procurement" if that should be necessary, more encouragement for "new science based foreign policy initiatives and opportunities for international cooperation" and a continuing interest in the development of science policy as such.

TASK FORCE REPORT

No Immediate Prospect

The reaction of the Administration to the publication of the Task Force Report seems to hover between pleasure and embarrassment. There is, of course, no time for the report to have an influence on the budget process for the coming year, now well under way. The most likely development is that what the report has to say will in due course influence the budget proposals of the National Science Board (on behalf of the National Science Foundation) due to emerge in February next year.

One possibility is that the National Science Foundation may then be seen to be asking that more of its funds should be distributed according to the pattern originally suggested at the beginning of 1969, although there is every likelihood that the National Science Board itself is by no means clear in its own mind about the desirability of this new pattern, which would spend a greater proportion of the money needed for basic research in the form of grants to departments and students not linked with specific research proposals. With Dr Philip Handler, the present chairman of the board, likely to leave later in the summer, it is on the cards that the board will want to think again about its commitment to this proposal.

Whether the National Science Board will be encouraged by the Administration to a more ambitious view of its responsibilities is also problematical—certainly there is no immediate sign of a public declaration by the President about the importance of science and of graduate education—this would no doubt seem a little like signing a blank cheque. The real test will be the extent to which the National Science Foundation is encouraged to bid for more money twelve months from now.

On the larger question of the form of organization needed for planning the development of science and technology, the task force has avoided reference to some of the more daring schemes that have recently been talked of—the proposal for setting up the National Institutes for Research and Advanced Studies put out by the Daddario committee some weeks ago, for example. But, on the other hand, the task force has branched out vigorously on its own with the proposal that the Federal Council for Science and Technology should be given the power to coordinate the scientific work of the mission agencies even to the extent of making sure that Federal Government laboratories are properly integrated with the rest of academic life. Few agencies will welcome this proposal, even though there is no obvious reason why the federal council should not undertake this kind of coordination without formal direction from above.

UNIVERSITY OF WISCONSIN

Looking for a President

from a Special Correspondent

THE latest to join the long list of institutions seeking new presidents is the University of Wisconsin, a huge land-grant multi-versity with sixteen campuses and a liberal tradition centred in an essentially rural state. Only a few hours after he had returned to Madison from Washington, where he and seven other "élite university" presidents tried to persuade President Nixon to cool the Administration's attitude towards students, Fred Harvey Harrington surprised nearly everybody by announcing his resignation.

There was a bit of irony in Harrington's resignation. He is a recognized authority in the field of American policy in the Far East, and has been an adviser in this area to Presidents Eisenhower, Kennedy, Johnson and Nixon. He gave up his $47,000 a year job as president to become a $35,000 a year history professor, effective from October 1, on the fourth day of rioting on the campus, touched off by the decision to expand the war into Cambodia. In recent years, Harrington had clashed often with some of the regents and with several state legislators. One state senator from a northern rural area of Wisconsin carried on a campaign against the university's president and passed out automobile bumper stickers reading: "Harrington Must Go". Generally, Harrington was popular among the students. Several regents urged that he take a tougher line on students although they were unable to define exactly what they wanted. Harrington told a news conference that his resignation had been "long-planned" and he denied that he had been dismissed. "The timing is accidental," he said.

In spite of everything, Wisconsin is viewed by many as one of the great universities. It is especially strong in the physical and the biological sciences. It has been the home of two recent Nobel laureates, Joshua Lederberg and H. Gobind Khorana. But Stanford stole Lederberg and the Massachusetts Institute of Technology lured Khorana after they received their prizes in Stockholm. Tight budgets, enforced by the legislature and the regents, have made it difficult for administrators at Wisconsin the last two years. In addition, a strict quota restriction on students from out-of-state has been adopted; there have been allegations that these quotas are aimed at prospective students from such states as New York, New Jersey and Connecticut which, through the years have been sending their "Harvard rejects" to Wisconsin. Some have even suggested that these restrictions are aimed, directly or indirectly, at sons and daughters of Jewish families because quite a number of out-of-state students at Wisconsin are Jewish.

Harrington graduated from Cornell University and took a doctorate from New York University in 1937. He came to the Middle-West and, for a number of years, was chairman of the department of history at Wisconsin before his nomination to become president. He was a leader in the formation of two middle-western consortiums for higher education—the Argonne Universities Association, which is the policy-making body of 39 institutions concerned with the long-range plans of the Argonne National Laboratory, near Chicago, and the Committee on Institutional Cooperation, concerned with inter-disciplinary studies, mainly in the sciences, linking nine public and two private universities from Ohio to Iowa.

Now that Harrington is "out", it will be especially interesting to see who will become the fifteenth president of the University of Wisconsin. The tradition has been to find, if possible, a man within the system rather than to go outside. One possibility is another historian, Irvin G. Wyllie, the scholarly chancellor of the university's new Parkside campus near Kenosha. He has been building a new campus and a new faculty and, to date, has not been scarred by the student revolt.

To California without Smoke

THE strangest by-product of the campaign against pollution, the Clean Air Car Race between Cambridge, Massachusetts, and Pasadena, California, seems destined to crowd the transcontinental roads even more tightly this year, in the week of August 24. So far, 35 entries have been registered, and it is expected that there will be further entries from at least two university teams anxious to explore the virtues of liquid hydrogen and liquid oxygen as propellants for road vehicles. So far, however, most interest centres on a mystifying entry from the University of South-eastern Massachusetts, whose entry is said to require no fuel and no supply of energy at stopover points. Speculation ranges from gyroscopically driven vehicles to wind-driven road yachts, although the fixed route prescribed for the race will presumably prevent the kind of tacking that would make arrival at the California Institute of Technology an uncertain process.

The two originating colleges, MIT and Caltech, will be responsible for testing all entries for safety before they take the road. The previous race, in 1968, involved two electrically driven vehicles racing in opposite directions across the United States. This year, both MIT and Caltech (which won last time) will enter two comparatively clean vehicles. The MIT entries include a car with batteries which are charged intermittently by means of a petrol driven engine—the device is expected to be less polluting than a simple internal combustion engine—and a turbine driven electrical generator driving an electric motor which will weigh 225 pounds and generate 45 kW amperes. The second of these two cars breaks new ground by using an electric drive motor capable of delivering up to 600 horsepower and weighing close on half a ton. Although the turbine should produce much less pollution in its exhaust than a conventional engine, there will still be some nitrous oxide.

The occasion of the race has provided General Motors, recently much maligned by student groups, with an opportunity to contribute twenty new cars and $40,000 to the committee responsible for the race. The largest entry is expected from the Worcester Polytechnical Institute, which is expected to enter six cars, some driven by steam and some by electricity.

SCIENCE BUDGET

Unaccustomed Gentleness

THE Appropriations Committee of the House of Representatives has this year dealt more leniently with the National Science Foundation than its practice in the past few years had led many people to expect. The National Science Foundation budget for the year beginning in July, if the Appropriations Committee has its way, will be $497 million, $16 million less than the sum of $530 million asked for in the Administration's budget. These sums of money include both the allocations for the Sea-Grant colleges, intended to stimulate research in oceanography, and the comparatively small sum spent by the National Science Foundation outside the United States. In its recommendation to the House of Representatives, the Appropriations Committee says that it approves of the National Science Foundation's growing interest in problems of a practical character—the environment for one. It does, however, also specify that the level of expenditure on summer institutes should be maintained at its present level—equivalent to $23·3 million—and not cut in half as the Administration has suggested. This means that the National Science Foundation will have less leeway in its planning than the comparatively small overall reduction would suggest, but there has nevertheless been a good deal of relief, both at the National Science Foundation and the Office of Science and Technology, that there will be an increase of something exceeding $57 million in what the National Science Foundation has to spend next year.

By all accounts, the Appropriations Committee considers that an increase which amounts to more than 12 per cent from one year to another must surely be sufficient. In practice, the budget will eventually be determined by whatever compromise is reached between the Appropriations Committees of the Senate and the House of Representatives, while the amount of money which the foundation has to spend will be determined by how the Administration chooses to live within the limits set by Congress. There is, however, a good chance that the Senate will take a more generous view than the House of Representatives has done, so that even though the budget may not be as great as the optimists expected, it may eventually turn out to be a little better than at present.

HELIUM

Intimations of Mortality

ONE of the unsung casualties of the impending restriction of federal money is the Helium Research Center at Amarillo, Texas, a laboratory of 65 souls set up in 1960 as part of the Federal Government's Helium Conservation Program. According to an official of the programme, which has only recently been set up independently of the Bureau of Mines (on April 1), it will be possible to employ 14 of the people displaced in other parts of the conservation programme, especially on the analytical side. The laboratory as such will, however, shut down at the end of the financial year on June 30, chiefly because of the vigorous steps being taken by the helium programme to economize on its budget, which at present amounts to $50 million a year, and partly because of the view, disputed by some of those at the laboratory itself, that the laboratory's work is only indirectly relevant to that of the helium programme itself. In fact, the centre has been concerned with the thermodynamic properties of helium and mixtures of helium and nitrogen—matters of great importance in determining how helium bought under the conservation programme should be paid for, the development of analytical techniques and the preparation of exceedingly pure quantities of the gas for physical work. By all accounts, the decision to close the laboratory is extremely sudden—indeed, the federal budget for 1971 includes $1·3 million for the laboratory, evidently now to be saved.

The closing of the laboratory will draw attention yet to the continued difficulty of operating the Helium Conservation Program, said to have been under review for the past year. At the helium office earlier this week, an official said that attempts were being made to save money not merely by closing down the Helium Research Center, but by economizing on headquarters staff and by consolidating the cryogenic operations involved in the production of helium at the Exell plant in Texas. What has forced the programme into difficulties is the failure of the demand for helium to grow as quickly as had been expected some years ago, when prices were fixed for the purchase and stockpiling of helium extracted from the natural gas of Texas, a unique resource in which helium may constitute between 0·4 and 2 per cent of total volume. In the present decline of the market, it has been possible for private operators to undercut the government's selling price of $35 per thousand cubic feet by up to a third, in the process winning a dominating place in the private helium market.

The principle on which the Helium Conservation Program operates is that the government buys at $12 per thousand cubic feet and sells at $35 per thousand cubic feet, stockpiling the gas in underground reservoirs and planning to recover the cost by eventually selling off the helium to what is expected to be a growing market. The original calculation, in 1960, was that the programme would liquidate itself in 35 years. In practice, demand for the gas has not increased as quickly as expected, while the government's share of the market has been restricted by the activity of the private operators to the public domain. In ten years, the Federal Government has spent close on $300 million on buying and storing helium. Over the years, the cost of this investment has increased with the cost of money, which is another reason why the programme should now be regarded quizzically. It is, however, hard to see how the Federal Government can wash its hands entirely of helium conservation—it is reckoned that something like 60 per cent of all the helium emerging from the ground in Texas finds its way into the hands of the conservation programme or of the private operators. From the National Academy of Sciences to the Office of Science and Technology, with the US Navy included, the government would be hard put to remain in the helium business. Its most likely response, in the present financial climate, would be to find some way of driving up the selling price for helium, either by outbidding the private companies for supplies or by the old fashioned but direct approach of creating a monopoly.

UNIVERSITIES

Moderation at Boulder

from a Special Correspondent

Boulder, Colorado

A NEW moderate trend is discernible among protesting students. This has been particularly well exemplified on Colorado campuses in the past week. During an "official" two day strike at the 20,000 strong university of Colorado at Boulder, the university's president, Dr Frederick Chieme, was given an ovation when he addressed a rally packed by half the university population (10,000). The students were calling for a complete shutdown of courses for the rest of the term. The object apparently is to conduct house to house teach-ins of the uncommitted "civilian" community. The president proclaimed that he was "bitterly opposed" to the war in Vietnam and for this reason was against closing the university "so that we can make our voices heard".

The moderation of the manifestations, despite the undoubted strength of student feeling there can, in part be attributed to the wise handling of the crisis. The university has a famous sociology department, and the departmental head, Professor Howard Higman, is chairman of the staff executive committee and vice-chairman of the university's governing body. An analysis of options open to the university government showed seven possibilities, ranging from severe penalties for students missing class to total capitulation—that is, shutdown of the campus.

The committee has set its face against bringing in the police, much less the National Guard, under almost any circumstances. After lengthy debate, the council voted 33 to 5 for "business as usual", with a lenient line on grading those who do not attend classes. This week will show what the student response is. Some face loss of degrees if they are not graded or examined this term, which ends anyway in three weeks' time. At other nearby institutions, moderate students have been physically interposing themselves between the authorities and extreme groups bent on violence. A line of passive defenders of their own people has in some cases been enough to turn back student wreckers.

Midweek, there was a much smaller turn out of striking students in Denver itself. A demonstration only a few hundred strong halfmasted the stars and stripes on Capitol Hill and tucked a red flag under the arm of the Union soldier on the Civil War memorial in front of the Capitol building. There was almost a holiday mood about the affair. There was also an air of family picnic prevailing at the start of the massive and highly organized Saturday rally on Capitol Hill. A march of up to eight or nine thousand students passed off without incident, largely due to excellent marshalling by student organizers themselves. They meticulously observed the police regulations for the march that demonstrators should keep the sidewalks clear. Legal marshals from Denver Law School mingled with the marchers and on Capitol Hill (where the crowd reached 12,000) to maintain discipline and to advise. A briefing prepared by the law school marshals and circulated in advance clearly set out to the demonstrators their rights and obligations and what to do if "busted". "If tear gas is used—don't rub your eyes," it concluded. A contingent of 200 medical students, both girls and boys, provided volunteer Red Cross units equipped with walkie talkies and placed at strategic points as much to set an example and head off trouble as to mop up casualties afterwards. There were none. The speakers' microphone at the Capitol was briefly taken over to preach revolution but was soon returned to the hands of the organizers. The police actually supervised the lowering of the national flag as the acting governor (Hogan) had given permission for this. Four objectors were put aside. The only arrest occurred after the scheduled meeting was over when extremists picketed the police station and refused to move from a busy street crossing where they stayed on and staged a sitdown in the road.

CANADIAN ASTRONOMY

Boost for New Institute

THE new Interdepartmental Institute of Astronomy and Space Science at the University of British Columbia, Vancouver, has been given a good start by the National Research Council of Canada in the form of a grant of $538,600. The intention is that the institute should work closely with the Astrophysics Branch of the Radio and Electrical Engineering Division of the National Research Council. This should give the institute easy access to the two major observatories in British Columbia—the Dominion Astrophysical Observatory at Victoria, and the Dominion Radio Astrophysical Observatory at Penticton—which are managed by the Astrophysics Branch.

It seems that the Vancouver institute will specialize in radio astronomy at centimetre wavelengths and less, and in plasma physics. Radio astronomy at short wavelengths is hampered by the presence of water vapour, but there are sites in Western Canada which ought to be suitable because of their height and the coldness of the atmosphere. One of the projects is to develop a 15 foot dish aerial which has an accurate enough surface to work at wavelengths of a few millimetres. The intention here, of course, is to break into the new branch of radio astronomy which deals with the detection of molecules in interstellar clouds by the short wavelength radio waves that the molecules emit. This work will be under the direction of Dr W. L. H. Shuter, associate professor in the Department of Physics. Shorter wavelengths in the no-man's-land where radio and infrared wavelengths merge will be the responsibility of Dr M. W. Ovenden, professor of astronomy in the Department of Geophysics, and part of the effort here will be in developing more efficient detectors.

The third area which will be dealt with at the new institute, plasma physics, is to be covered by Professor R. Nodwell of the Department of Physics.

The grant comes under an NRC scheme to encourage new, and especially interdisciplinary, research centres. Spread over three years the grant will be $315,800 in 1970–71, $144,800 in 1971–72 and $78,000 in 1972–73.

NEWS AND VIEWS

Making Proteins in Higher Cells

MOLECULAR biologists who have started to elucidate the mechanism of protein synthesis in nucleated cells are in the envious or invidious position of knowing what the results of their experiments should be because they already know in detail how bacteria make proteins. The synthesis of protein in microorganisms and eukaryotes is certain to be basically similar, but there are bound to be some differences. Until recently two technical problems have bedevilled attempts to sort out the similarities and differences; the first was selecting a eukaryote system amenable to precise analysis; the second was devising experiments which take advantage of available knowledge of bacterial protein synthesis but which do not preclude the possibility of revealing the idiosyncrasies of eukaryote cells. The disarray among groups studying the initiation of protein synthesis, which has been revealed in *Nature* (**226**, 414; 1970, and this issue, pages 607 and 610), proves how real these difficulties have been.

In bacteria, initiation of protein synthesis depends on the incorporation of formyl-methionine, a methionine residue with its amino group blocked by formylation. The formyl-methionine is carried to the ribosome by a unique species of transfer RNA which can both recognize the initiator sequence, the capital letter in a messenger RNA, and allow the formylation of the methionine residue it carries. Once the protein has been made in the cell the formyl group is always removed enzymatically, and sometimes the methionine residue is cleaved as well.

But which of these steps in initiation are universal and which are peculiar to bacteria? Is a blocked amino group the key characteristic of an initiator and is methionine always the initiating amino-acid? Two weeks ago (*Nature*, **226**, 414; 1970) Liew and his colleagues reported experiments which suggest that the f2a histone proteins in rat liver are initiated with an acetyl-serine residue. They injected rats with labelled acetate and labelled serine and were able to isolate histones apparently containing acetyl-serine, which could only be at the beginning of each histone polypeptide chain. This suggests that acetyl-serine can initiate the synthesis of histones, in which case a blocked amino group would seem to be the crucial characteristic of an initiator.

In this issue of *Nature* (pages 607 and 610), however, Smith, Marcker and Brown report more clear cut experiments leading to a different conclusion. Marcker's group is exploiting an *in vitro* system in which RNA isolated from EMC virus, or synthetic messenger RNA, is faithfully translated by cellular machinery extracted from Ehrlich ascites cells (*Nature*, **225**, 184; 1970). Like the familiar bacterial cell-free systems on which it was modelled, the ascites cell-free system can be precisely characterized and many of the ambiguities inherent in all experiments involving animals or cells, including those of Liew *et al.*, can be eliminated.

Smith and Marcker (page 607) have now detected two species of methionine transfer RNA in Ehrlich ascites cells, mouse liver and yeast which seem to be precisely analogous to the two species of methionine tRNA in *E. coli*, one of which is the specific initiator tRNA. Like its counterpart in bacteria only one of the two eukaryotic methionine tRNAs incorporates methionine in the initiating position when the Ehrlich ascites cell-free system is primed with synthetic messengers of known composition. The second species of methionine tRNA in nucleated cells, again like its bacterial counterpart, incorporates methionine internally into growing polypeptide chains. Furthermore, the initiating methionine tRNA in eukaryotes, but not the species responsible for incorporation of methionine internally, can be formylated by the formylation enzymes of *E. coli*. Surprisingly, however, eukaryotic cells do not contain transformylases and the initiating methionine is not formylated. A blocked amino group cannot therefore be a prerequisite of an initiating amino-acid.

The most compelling interpretation of these findings is that methionine is the universal initiator of bacterial and eukaryotic protein synthesis, and that the only significant difference is that the methionine residue is formylated in bacteria but not eukaryotes. And because few eukaryote proteins begin with methionine and at least one EMC viral protein made *in vitro* begins with alanine, the initiating methionine residue is presumably cleaved more often from completed eukaryote proteins than from completed bacterial proteins.

There are, of course, as Smith and Marcker point out, two other interpretations of their results. The initiator methionine tRNA could be one of several tRNAs specialized in eukaryotes for initiation. Alternatively the methionine tRNA might simply act by fixing the reading frame without the methionine residue being involved in formation of the first peptide bond. In this case initiation would depend on the methionine tRNA but the polypeptide chain could begin with any amino-acid with or without a blocked amino group. Both these models, however, seem destined to be short-lived. Brown and Smith (page 610) have all but eliminated the first. They find that, at low concentrations of Mg^{2+}, of some twenty synthetic messengers tested only that with the AUG methionine codon near its beginning can be translated in the ascites cell-free system, although the cell-free system contains all species of tRNA. The Cambridge group is therefore convinced that the methionine tRNA will prove to be the unique initiator in eukaryotes.

Although these experiments show that AUG at the start of a synthetic messenger is read, with methionine incorporated as the first amino-acid of the polypeptide, it is conceivable that with natural messengers the initiating methionine tRNA merely fixes the reading frame. This seems unlikely, however. Already it is rumoured that groups in Britain and the United States are finding that haemoglobin made on reticulocyte polysomes begins with a methionine residue, which in the cells is subsequently cleaved. Furthermore, Sherman and his associates reported last year that cytochrome *c* made in certain mutant strains of yeast has a methionine in the N-terminal position, which is subsequently removed to expose the normal first amino-acid, threonine. The initiating methionine codon in eukaryotes seems, therefore, to be read as it is in bacteria.

The striking parallels between the initiation of protein synthesis in bacteria and nucleated cells apparently involve more than the use of methionine as an initiator. As Prichard and his colleagues reported last week (*Nature*, **226**, 511; 1970) there are three initiation factors in reticulocytes, similar to the three initiation factors in bacteria, which are required for initiation of synthesis of haemoglobin. Although the precise details of how each of the three mammalian factors functions have yet to be elucidated nobody will be surprised if they prove to play identical parts to the f1, f2 and f3 factors in *E. coli*.

LYMPHOCYTES

Cooperating Populations

from a Correspondent

THE interesting phenomenon of cooperation between two populations of lymphocytes in the immune response has been the topic of two recent meetings. A British Society for Immunology colloquium on "thymus-derived cells" was held at the National Institute of Medical Research, London (NIMR), on April 26 and a more general discussion of the topic was held at the Royal Society on April 30. There now seems to be agreement that the induction of antibody formation to many antigens requires an immunologically specific response to two distinct antigenic determinants by two distinct populations of lymphoid cells. The ultimate precursors of both populations come from the bone marrow, but one population (the T cells) requires, during its maturation, a sojourn in the thymus.

The T cells, said Dr A. J. S. Davies (Chester Beatty Institute), are capable of prolonged re-circulation, they respond *in vitro* to phytohaemagglutinin and populate the "thymus-dependent areas" of the peripheral lymphoid tissues. Although they certainly react with antigen through specific receptors and mediate delayed hypersensitivity and homograft rejection, they are not the cells that go on to secrete the serum antibodies.

T cells further carry on their membranes a specific allo-antigen, θ. Studies with anti-θ serum comprised the bulk of the work described from NIMR. Dr J. Owens described how lymphocytes develop θ antigen during their sojourn in the thymus, and Dr H. H. Wortis said that congenitally thymus deficient mice have no θ positive cells. Mr M. Raff showed that θ antigen is present on all lymphoid cells in the thymus, on 90 per cent of those in the thoracic duct lymph and on a variable proportion of those in the peripheral lymphoid tissues. This proportion is greatly reduced in thymus deprived animals or in those treated with antilymphocyte serum. Dr M. Greaves presented data to show that θ positive cells also carry receptors sharing the Fab determinants but not the Fc determinants of immunoglobulins. For this reason the group at NIMR postulates a distinct immunoglobulin, IgX, on the surface of T cells.

The second population, the cells that make the circulating immunoglobulins, are known as B cells to mark their association with the bone marrow. It became clear that less is known of their life span and recirculation than is the case with T cells. They carry immunoglobulin receptors on their membranes, which are believed to be representative as to class and to affinity of the product that they and their progeny are capable of secreting, but they do not carry the θ antigen.

Cooperation in antibody production has been demonstrated in two separate connexions. One is the formation of antibody to hapten in an animal immunized with hapten carrier complex. In this situation some specific response to carrier determinants is required for anti-hapten antibody to be made. The other is the requirement for both T cells and B cells in order to restore to an irradiated animal its capacity to make antibody to many antigens. Drs K. Rajewsky (Cologne), R. B. Taylor (Bristol) and others showed that it can be accepted that these are two aspects of the same phenomenon. The system devised by Dr N. A. Mitchison (NIMR) for showing this to be so is to transfer, into an irradiated recipient, thymus derived cells from one donor and bone marrow cells from another. The conclusion is that to make antibody optimally to a hapten it requires bone marrow cells primed to the hapten itself and thymus derived (helper) cells primed to the carrier. The elimination of helper cells by treatment with anti-θ and complement, as Raff showed, is further evidence that they are T cells.

Mitchison proposed that cooperation served as a mechanism for concentrating antigen at the B cell receptor, the high local concentration allowing relatively low affinity receptors to be triggered. This model provides an explanation for the observation that the cooperating cell is not needed when high concentrations of antigen are used, or with certain highly polymeric antigens which presumably can react with multiple receptors on a B cell.

The mechanics of cooperation are uncertain. One school of thought, represented by K. Rajewsky and R. B. Taylor (NIMR), believes that T cells and one or more B cells are brought into contact by antigen bound on their receptors. Doubts were expressed by Professors J. L. Gowans (Oxford) and J. Turk (Royal College of Surgeons) as to whether the conditions of cell to cell contact would always be met at sites where the cooperative immune response occurs. As an alternative, it was proposed by Dr P. J. Lachmann (Cambridge) that cooperation was mediated by an antigen-specific "macrophage inhibition factor" secreted by T cells, which binds to local macrophages and there presents antigen to the B cells.

The general validity of the model of cell cooperation that emerged from the two meetings seems to be established and marks an advance in knowledge of the immune response which should influence the planning and the interpretation of experiments throughout immunology. There are some topics—the function of the thymus hormone and antibody formation in humans with immune deficiency states and in chickens after bursectomy or thymectomy—where the implications are so vital that it is a pity that there was no opportunity to discuss them.

ALGAE

Remarkable Membranes

from our Microbiology Correspondent

THE gas vacuoles of the blue-green alga *Microcystis aeruginosa* have been found to have limiting membranes composed entirely of protein, without the lipids usually expected in biological membranes. Gas vacuoles, which are found in the cells of many blue-green algae and some bacteria, seem to regulate the vertical distribution of these organisms in water. Their most remarkable feature now seems to be their limiting membrane, as Jones and Jost have found recently (*Arch. Mikrobiol.*, **70**, 43; 1970).

They lysed algal cells by treatment with penicillin and prepared and purified vacuoles by a combination of liquid polymer partitioning and molecular sieving on 'Sepharose'. In this way the principal soluble and insoluble lysate components such as proteins, pigments, thylakoids and the polysaccharide α-granules were removed. Radioactive cross-contamination tests indicated that the final membrane was only 4 per cent contaminated by extraneous material. The membrane comprised a protein which had 52 per cent non-polar, 18 per cent basic and 10 per cent acidic amino-acids, from which imino and sulphur amino-acids were absent. Isoelectric focusing gave a value of 7 for the isoelectric point of the membrane protein, and its molecular weight was found to be about 14,000.

Membranes from gas vacuoles of *Halobacterium* are composed largely of protein, but allegedly contain nucleic acid and carbohydrate (Stoeckinius and Kunau, *J. Cell Biol.*, **38**, 337; 1968). Jones and Jost's findings, however, suggest that the non-protein components in the bacterial system are contaminants. Nevertheless amino-acid and density characteristics clearly distinguish the membrane protein of *Halobacterium* from that of *Microcystis*.

To complement the chemical data, Jost and Jones have made a structural analysis of the membrane of the gas vacuole of *Microcystis* (*Canad. J. Microbiol.*, **16**, 159; 1970). They found that the vacuole was 70 × 350 × 2·8 nm in size, and composed of a single layer of subunits 2·8 × 4·2 × 3 nm. Frozen-etched preparations show that the inner face of the vacuole has a ribbed appearance and that the ribs are made up from the protein subunits. Each turn of a rib is composed of about seventy subunits and the vacuole as a whole contains about 6,000 subunits. Measurements of folding angles in flattened vacuoles made it possible to determine a value of 25 nm for the distance between subunits in the ribs.

Clearly the membranes of gas vacuoles are very different from other biological membranes in which interactions between lipids and proteins are thought to define the structural and physico-chemical properties. The "unit membrane" concept is not appropriate to the gas vacuole membrane in which interactions are between proteins and proteins. The molecular organization of the membranes of gas vacuole remains to be deciphered, but such protein membranes may be derived from covalent linking analogous to the bacterial peptidoglycan, or non-covalent interaction of the type proposed for virus particle construction. Further investigations of these prokaryotic organelles will certainly be watched with interest.

SYNTHETIC POLYPEPTIDES

Models for Models

from our Molecular Biology Correspondent

ALTHOUGH it is true that the analogy between synthetic polypeptides and proteins, hard pressed in its day, is now barely discernible, these versatile molecules retain a certain fascination, and have become a study in their own right. At the same time the experimental and theoretical treatment of conformational transitions has been based to a great extent on synthetic homopolymers: they have provided the whetstone on which the tools fashioned for the assault on the structure of real proteins are still being sharpened.

The calculation of stable conformations of polypeptide chains is an activity that has so far been judged almost wholly on the basis of its success in predicting the known characteristics of synthetic polypeptides in solution. An interesting example here is the series of esters of poly-L-aspartic acid. Most of these form right-handed α-helices, but others turn out left-handed. Scheraga and his colleagues (Yan *et al.*, *J. Amer. Chem. Soc.*, **92**, 1109; 1970) have performed calculations of the conformations of the three isomeric chlorobenzyl esters (*ortho*, *meta* and *para*) of poly-L-aspartic acid. Their report rouses the confident expectation of a dramatic result—that these polymers, chemically so similar, will differ conformationally—and of the ineluctable convergence of theory and experiment. And so indeed it turns out. In order to improve the physical basis of the calculations, Scheraga and his colleagues have recently introduced molecular orbital methods for determining energy functions. Minimization of energy involves varying all dihedral angles in the residue and calculating a series of energy contributions for each combination. Two large contributions in the aspartates come from the interaction of the amide with the side chain ester dipole, and with the carbon-chlorine bond dipole. In all cases the dipole-dipole interaction energy is lower in the left-handed than in the right-handed conformation, but whereas in the *ortho* and *meta* polychlorobenzylaspartates it dominates the total energy difference between the two states, in the *para* isomer it is insufficient to overcome a torsional energy favouring the right-handed helix. The calculation, it must be said, is delicately poised, the result being a small resultant of large positive and negative terms. Nevertheless, examination of the three isomers (Erenrich, Andreatta and Scheraga, *ibid.*, 1116) bears out the prediction: in four helix-forming solvents the *para* isomer is plainly right-handed, as judged by optical rotatory dispersion, and the other two, with inverted Cotton effects, are left-handed.

Another finely balanced conformational situation occurs in poly-L-lysine and its homologues. Polylysine, as all the world knows, is a random coil in water at neutral pH, but becomes α-helical at high pH, when the side chains are deprotonated. Polyornithine, which has a shorter side chain by one carbon, also undergoes such a transition, but achieves only partial helicity. Hatano and Yoneyama (*ibid.*, 1392) have prepared the next lower member of the series, poly-γ-diaminobutyric acid, and this exhibits scarcely any helix at all at any pH, by optical rotation, circular dichroism and infrared spectrum. Evidently the formation of the polylysine helix depends on the long side chain (a curious result, in that polyalanine, for example, is helical when solubilized in water). When the ϵ-amino groups are blocked with carbobenzoxy functions, the polymers are insoluble in water, but in suitable solvents all are helical, and indeed it is the diaminobutyric acid helix that is most resistant to a helix-breaking solvent. Inter-side chain associations of differing strengths are postulated to account for the results.

A favourite polymer, the object of much experimentation over the years, is poly-L-proline. It has no internal hydrogen bonds, and exists in a left-handed and a right-handed form, the transition between them involving *cis–trans* isomerization about the peptide bond, which is a slow process. Mattice and Mandelkern (*Biochemistry*, **9**, 1049; 1970) have confirmed the surmise that the random coil also exists, and can be elicited by addition of calcium chloride to the aqueous solution. A theoretical analysis of the solvent-dependent transition between the helical forms, I and II, using the lattice formulation of Schwarz, is given by Gaser *et al.* (*Biopolymers*, **9**, 329; 1970) and the agreement with experiment is a telling demonstration of the capacity of modern theory to cope qualitatively and even quantitatively with conformational transitions in homopolymers.

RADIATION PROTECTION

Reducing the Rads

from a Correspondent

THE problem of protecting workers and the public from any harmful effects of ionizing radiation occupied members of the international radiation protection association at their congress in Brighton on May 3–8.

The congress president, Dr W. G. Marley (UKAEA Health and Safety Branch), said that this was an important and continuing task in the application of radiation for the benefit of mankind. The benefits of avoiding future detriment set against the marginal costs of reducing radiation doses led Mr H. J. Dunster (UKAEA Health and Safety Branch) to define a "justifiable dose". If the cost of dose reductions exceeded a few pounds per man rad he considered that the "justifiable dose" would not be much less than the "supportable dose" which was based only on comparison with radiation and other risks. Several other contributors used the man rad cost—the cost of reducing a man's dose by one rad as an aid to decision making between, say, alternative protection schemes or courses of radiotherapy. The International Commission on Radiological Protection (ICRP) fielded a strong team for a round table discussion on the basis and application of their recommendations. Dr E. E. Pochin said that although the accuracy with which risks were known was only approximate, rules and regulations based on ICRP recommendations were precise. Others referred to the biological insignificance of an individual receiving twice the maximum permissible dose, as recommended by ICRP, in one year.

The ICRP listed fruitful areas for research: on the shape of the dose–effect curve at low doses compared with the ICRP linear model and on the risk of taking particles of high specific activity into the body. There was no doubt that ICRP must continue to provide basic guidance on dose limits.

Dr R. H. Mole (MRC Radiobiology Unit) reported that increasing knowledge and understanding showed that none of the working hypotheses is true in more than a rather limited sense. He said that some of the new knowledge came from continuing the follow up of work on well-established groups of irradiated persons, but there was no more evidence than before of measurable effects from radiation exposure of the order of natural background. Dr W. L. Russell (Oak Ridge National Laboratory) reported mechanisms of genetic recovery which ranged from the repopulation of the spermatogonia in the testis to the more direct recovery arising from the repair of mutational and premutational material at the molecular level.

The natural background still attracts considerable attention although situations studied often involve the exposure of only a very few people. Several contributors, notably Dr M Suomela (Institute of Radiation Physics, Helsinki), reported radiation exposure following the ingestion of water rich in radon-222. There is encouragement for studies of the metabolism of plutonium in the commercial prospects of nuclear power from this element. Suggestions for the treatment of plutonium contamination of the lungs included the use of chelating agents in aerosol form as a convenient long term treatment.

Dr G. M. Obaturov and others from the Ministry of Physics and Power Engineering, USSR, compared the absorbed dose in a human body for neutrons incident from different directions with Snyder and Neufeld's unidirectional data, and concluded that a large correction factor was necessary. A method of applying this correction was suggested by Dr J. Neufeld (Oak Ridge National Laboratory), who proposed a quality index defined as the ratio of the maximum dose equivalent in a phantom (DE$_{\max}$) and a reference dose (D$_{\rm R}$) which could be the absorbed dose in soft tissue in an unperturbed radiation field. The quality index would then be used together with the reference dose to predict dose equivalent.

The potential release of fission products to the atmosphere due to reactor accidents requires constant vigilance in the metabolic pathways to man. Nuclides usually considered to be most important are iodine, strontium, caesium and ruthenium. Most speakers agreed that iodine was likely to be the dominant cause of radiation exposure (unless the reactor system is designed to control iodine release). Dr R. Scott Russell (ARC Letcombe Laboratory) said that in most Western countries the critical pathway is still by way of milk from cows and that strontium-89 is likely to be more significant than strontium-90 in the early stages of a release.

INVERTEBRATES

Discovery in Devon

THESE fearsome little creatures have been discovered between the sand grains of the Exe Estuary in South Devon during an ecological survey of free living nematodes. These two, the male (*a*) and female (*b*) of *Enoplolaimus denticulatus*, belong to one of fourteen new species of nematodes described from the estuary by R. M. Warwick (*Bull. Brit. Mus.* (*Nat. Hist.*) *Zool.*, **19**, No. 4; 1970). On the basis of Warwick's measurements of six specimens of *E. denticulatus*, the heads in the picture are likely to be about 0·05 mm in diameter. Males were on average 3·7 mm long and females 4·3 mm long; this is apparently a relatively large member of the genus.

METABOLIC DISEASES

More Clues from Enzymes

from our Medical Biochemistry Correspondent

NEW methods of diagnosis may be possible for two serious conditions involving inborn errors of complex lipid metabolism. They could stem from the results of enzyme assays of cases of Fabry's and Tay-Sachs diseases.

Fabry's disease seems to result from a lack of galactosyl hydrolase, which acts on the glycosphingolipid galactosyl galactosyl glucosyl ceramide, known as GL-3. Patients with this disease accumulate GL-3 in their plasma, urine and most tissues. The enzyme is found in a particulate fraction in normal spleen small intestine, kidney, brain and liver; it is absent from the mucosa of males with Fabry's disease and present in smaller than normal concentrations in tissues from heterozygous females (this disease is sex linked). Mapes *et al.* (*FEBS Letters*, **7**, 180; 1970) have found that normal human plasma contains at least one enzyme with this activity, whereas the plasma of patients contains no detectable GL-3 galactosyl hydrolase activity.

In the plasma of four normal subjects they found maximum GL-3 galactosyl hydrolase activity at *p*H 5·4 and 7·2, which probably means that two different enzyme molecules catalyse the same reaction. The optimum activity at *p*H 5·4 is similar to that found in the tissues; the four normal subjects all had about sixteen units of activity in their tissues at this *p*H. In the patients there was no activity in the plasma at either *p*H, which means that their plasma could not contain more than 1·5 enzyme units. The activity of GL-3 galactosyl hydrolase in the plasma not only provides an easy method of diagnosis, but also suggests that the condition could be treated. If the normal plasma enzyme activity could be restored artificially the accumulation of glycosphingolipid in the tissues might be prevented.

Tay-Sachs disease is a similar condition which is usually rapidly fatal, and Schneck *et al.* (*Lancet*, i, 582; 1970) have shown that it can easily be diagnosed before birth. They investigated a subject who had given birth to a child who died from Tay-Sachs disease, due to the absence of hexosaminidase A activity—the enzyme hexosaminidase is normally present as fractions A and B. They removed amniotic fluid at fifteen and twenty weeks in a later pregnancy and assayed it and uncultured foetal cells for hexosaminidase A activity, which turned out to be present in trace amounts only. By contrast, uncultured cells from a normal subject contained 28 per cent hexosaminidase in the A form. When the pregnancy was terminated the foetal brain contained 4·5 times as much of the ganglioside GM2 (which is cleaved by hexosaminidase A and B) as a normal foetal brain at fifteen weeks.

The results of the enzyme assays show that it is easy to detect Tay-Sachs disease according to the level of activity of hexosaminidase A at a relatively early stage in pregnancy without the need to culture foetal cells. Schneck *et al.* point out that if further work substantiates their findings effective genetic counselling will be available for the first time for mothers of infants with Tay-Sachs disease.

BRAIN CELLS

Neurones that Count

from our Neurophysiology Correspondent

A TEAM at the University of California claims that the cat's brain contains cells which count. R. F. Thompson K. S. Mayers and C. J. Patterson (*Science*, **168**, 271; 1970) have found that certain cells in the "associative cortex" apparently respond to a particular stimulus in a sequence of stimuli, for example, the fifth or seventh. Thus these cells seem to be coding for number.

The "receptive field", a concept introduced by Adrian in 1929, has become the investigational unit of neural coding. For example, neurones in the cat's visual system can be classified in terms of their responses to light stimuli of varying size, shape, brightness and duration delivered to that part of the retina stimulation of which changes their probability of firing. This is the cell's receptive field, and similar definitions can be made for receptive fields of neurones in other sensory systems. The adequate stimulus for a particular receptive field in the visual system comes from a hierarchy of increasing complexity, from spots of increased brightness or dimness, through edges, bars and slits, to figures containing angles. It is obviously difficult to maintain that the hierarchy will extend to include "gnostic" neurones with receptive fields that need very precise stimulation with complex patterns such as those presented by a mouse, but at least the initial hierarchical stages of pattern recognition seem to have an anatomical basis.

A further elaboration of receptive field is the class of abstraction, for example, recognition of number, which a cell might perform, and so it is interesting that Thompson *et al.* have reported the discovery of neurones sensitive to number in the "association" areas of the cat's cerebral cortex. They recorded the electrical activity of single cells in the brains of anaesthetized cats. The stimuli were sequences of clicks, light flashes or electric shocks, and different neurones responded with an increased probability of firing after different numbered stimuli.

Thompson *et al.* claim that the response is independent of stimulus modality and rate and is repeatably evoked during a long sequence of stimulus presentations. They report the discovery of five counting cells, encoding the numbers 2, 5, 6 (twice) and 7, from an investigated sample of 500 cells. The sequences were of ten stimuli repeated ten times. Within the responses recorded from the cells mentioned the grouping of discharges for particular stimulus number is significantly non-random. But, without a demonstration that such results could not be expected from random sampling of a population of 500 cells, it is better to reserve judgment on the existence of counting cells. It is clear that the cerebral cortex can in some sense count, but there is no *a priori* reason to expect encoding of number to occur at a single-unit level, although it must be expressed as a change in unit activity, though not necessarily in the activity of single, "gnostic", neurones.

HORTICULTURE

Pests of all Sizes

by our Botany Correspondent

GARDENERS who swathe their fruit bushes in string and cotton to protect them from the ravages of birds should be heartened to know that their method has been validated at the East Malling Research Station. The latest annual report from this centre of fruit growing research (price 21*s*) relates how 1 per cent of flowers were injured by house sparrows on blackcurrant bushes surrounded by strands of black thread, while on unprotected bushes 80 per cent of flowers suffered. When harvest time came the protected bushes provided an average of 3·7 berries per truss, compared with 1·1 from unprotected bushes. The respective yields were per bush 222 and 66 grams. A similar scheme is on trial with cherry trees, which have long suffered from hungry birds at East Malling. Trials with trees enclosed in bird proof netting supported on poles are to be extended next year.

During the past year there have as usual been further successes in the continuing battle against viruses. The widely used method for producing material free of viruses by culturing the growing tips of plants treated with heat, to eliminate the viruses, is proving useful with strawberries. Twelve clones freed of viruses in this way have cropped normally in their second year and are now available for release. Several hundred tips of hop have now been set up in culture, but so far no plantlets are ready for transfer to pots. These methods have also been successful with apple, pear, plum and cherry.

Heat has also been used in attempts to rid cherry budwood of overwintering populations of *Pseudomonas morsprunorum*, one of the causes of bacterial canker. Results so far suggest that it is difficult to kill the pathogen without also killing the buds. Treatment with streptomycin, however, seemed to be more promising; after immersion for six hours in 200 or 500 parts per million of the antibiotic, no colonies of the bacteria were detected on treated buds. One of the problems of this work has been identifying *P. morsprunorum* on untreated buds, and so high priority is to be given to improving techniques for isolating the organism.

The microflora of the surfaces of apples are also being identified, in the hope of achieving a better understanding of the way in which non-pathogenic fungi and those able to cause rotting compete for essential nutrients, and also of the changes in the microflora in relation to storage conditions and ripening. So far several yeasts have been identified, including *Torulopsis*, *Candida* and *Rhodotorula*. Fungi present include *Cladosporium*, *Alternaria* and *Phoma*.

CARBON FIBRES

Anisotropic Pores

from our Materials Science Correspondent

Now that it is widely known, in outline at least, how carbon fibre with optimum properties can be manufactured, interest increasingly focuses on the physical properties of the end-product and the way in which the structure correlates with the preparation parameters. For this purpose Ruland in Belgium has been using small-angle scattering of X-rays for several years (*CR Acad. Sci.*, **269**, 1597; 1969). D. J. Johnson and C. N. Tyson at the Textile Physics Laboratory at the University of Leeds have also been applying the technique, and they have recently published some of their findings (*J. Phys. D.*, **3**, 526; 1970).

The angular distribution of small-angle X-ray scattering is particularly sensitive to heterogeneities of electron density and thus to porosity, and it is possible to assess the anisotropy of pore shape. There are alternative theories of interpretation, which presuppose hypotheses about the statistical distributions of pore sizes, but Johnson and Tyson use various internal checks which diminish the arbitrary element in interpretation. They used Rolls-Royce carbon fibres, presumably made from polyacrylonitrile (PAN) and graphitized at different temperatures. Mean pore size and crystallite size and mean surface area of pores were deduced from X-ray scattering measurements as a function of graphitizing temperature and correlated with tensile strength. The latter peaked at 1,250° C, while the pore size suddenly increased at 1,900° C (with, however, no associated discontinuity in measured strength). For the highest graphitizing temperatures, pore size and modulus varied little but strength was not reproducible. The 1,900° C discontinuity is attributed to the plentiful breaking of cross-links, which leaves the structure in a "labile" state.

MOON

Gold and the Glassy Craters

by our Astronomy Correspondent

ONE of the more awkward discoveries of the Apollo 11 mission is that small craters between 20 cm and 1·5 m across, frequently contain lumps of soil coated on their top surfaces with glass, but Professor T. Gold's explanation of this phenomenon in terms of a solar flare powerful enough to cause glazing within the craters has not been immediately accepted (*Science*, **165**, 1345; 1969). The problem is, of course, to invoke glazing within the craters and nowhere else, for there is no evidence that the glazed patches have anything to do with the glass beads which make up such a significant part of the lunar soil. This is why Gold hit upon solar heating as the mechanism, because calculations by D. Buhl, W. J. Welch and D. G. Rea in the *Journal of Geophysical Research* indicate that the temperature within the craters is likely to be 10 per cent or so higher than that of the surrounding lunar surface when the Sun is above the horizon (**73**, 5281; 1968). Thus Gold proposed a solar flare which would have been just powerful enough to start melting the soil within craters but to leave the surface intact.

Obviously people are finding the degree of selectiveness necessary for this process hard to accept, and three papers challenging, or at best expressing doubt, about Gold's hypothesis appear in a recent issue of *Science*. J. Green of the Douglas Advanced Research Laboratories, for example, who shows his hand at the start by admitting his belief that almost all the major surface features are volcanic in origin, finds it easier to believe that volcanic bombs are responsible both for the craters and the glassy patches which they contain (**168**, 608; 1970). Volcanic bombs are large blobs of molten lava protected by a solidified crust which are thrown out of volcanoes. On impact they could produce a crater and their molten contents are likely to freeze rapidly in the lunar environment to leave behind the glassy patches.

Then E. D. Dietz and P. J. Vergano of Owens-Illinois Inc. of Ohio, famous for its glass–ceramic telescope mirrors, point out that the appearance of the glassy patches on the Apollo 11 photographs do not match what might be expected for the glazing of basalt by solar heating (**168**, 609; 1970).

Finally W. R. Greenwood and G. Heiken of the Houston Manned Spacecraft Center suggest that the glass is lunar surface material fused by the impact of the meteorite producing the crater and which has fallen back after the explosion to land on the crater floor (**168**, 610; 1970).

But although Gold agrees that the solar flare hypothesis is not strong, he refuses to accept that the alternatives are any better (**168**, 611; 1970). The drawback to the meteorite hypothesis, for example, is that the explosions are violent enough to make it unlikely that material would fall back precisely to the centres of the craters where the glassy patches are found. Gold also points out a general drawback to theories which have the glass formed at the same time as the craters. Because the glass appears to be barely eroded at all, the implication is that the craters have not been modified since their formation, and this is hard to square with what is known about the size distribution of meteorites.

Thus even Gold would seem to agree that the explanation of the phenomenon is still in doubt. Obviously everyone would like to get their hands on a sample of the glass, but unfortunately this is something that neither Apollo 11 nor 12 was able to provide.

BANDS

Contours from Photons

by our Solid State Physics Correspondent

ONE of the highlights of physical chemistry in the past few years has been the emergence of photoelectron spectroscopy as a means of studying the energy levels in molecules. This has been accompanied by a growing interest in what can be accomplished in solids with photoelectrons, and G. D. Mahan has now suggested that the angular dependence of photoemission should give important clues to the band structure of metals (*Phys. Rev. Lett.*, **24**, 1068; 1970).

Mahan has pursued a calculation for the case of sodium, which seems to be the customary metal on which to test new theories. He shows that electrons excited by a band to band transition in the metal which then leave the solid without being scattered are emitted in a highly anisotropic pattern, which is closely related to the characteristics of the conduction band. The details of photoemission are determined by how a series of cones, dependent on successive reciprocal latticed vectors, is projected outwards through the surface of the material.

For a given frequency of photon, the electrons in sodium have a well defined energy for a particular direction of emission. To calculate the intensity of the electrons, Mahan evaluates the Green's function for the electrons and interprets the resulting intensity distribution in terms of a free electron model. He deduces some typical intensity contours, which must be supplemented by the smooth background from electrons scattered both in the bulk material and by the surface.

To be useful, the technique must be applicable to metals with more sophisticated band structures. Mahan contends that a profitable way of proceeding is to postulate a form of pseudopotential with a number of parameters, calculate the general form of the intensity contours from the pseudopotential, and then set about a least squares fitting operation to give the best value of the parameters from the data. This does not avoid the task of finding the right sort of pseudopotential in the first place, but it does suggest that the scattering data will be quite exacting on the theory, which is the next best thing.

Molecular Markov Processes

by
M. R. HOARE
Department of Physics,
Bedford College,
Regent's Park, London NW1

Markov processes are encountered in many contexts in physics and chemistry. This review surveys the scope of their application.

THE research worker meeting Markov processes for the first time can be excused a feeling of surprise that such an apparently all embracing concept should have appeared even later in theoretical physics than on the more public side of probability theory. A term which can usefully be applied to subjects as diverse as the weather, the form of a racehorse, note patterns in music or the migration of labour could hardly fail to play as ubiquitous a part in pure science. Yet, although the notion of a Markov process is implicit in some classical studies—for example, the work of Rayleigh[1]—the term has only quite recently entered the physico-chemical vocabulary and is still denied some of the unifying influences it deserves.

When their basic generality is appreciated, a list of common physical Markov processes reads with all the diversity of the examples just given: configuration and growth kinetics of polymer chains, the slowing down of a neutron or hot atom, enzyme reactions, noise in electrical circuits, growth of condensation nuclei, dielectric relaxation. . . .

Their common characteristic is that they can all be represented as the average over an evolution, whether in space or time, of an ensemble of independent sub-systems each of which may undergo change between well defined states with prescribed transition probabilities. Moreover, the latter can be approximated, at least, as being a function only of initial and final states in a transition that is as independent both of the nature of previous steps and the probability of occupation of the states themselves. This restricted dependence on past history, which is the essence of the Markov process, often arises quite naturally in a physical model. For example, a molecule in a dilute gas "forgets" its past dynamics during the mean path between collisions and on next colliding scatters with probabilities determined only by its present velocity; the orientation of links in a polymer chain may be made independent of previous configurations by restricting the excluded-volume effect, and so on.

Mathematics of Markov Processes

Mathematically, the effect of the restrictions is that the transport equations for the evolution of probabilities in the space of states are reduced to linear form in which their solution is usually possible, at least by numerical methods. With this built-in loss of memory the Markov process might be described as "partially deterministic", occupying a position somewhere between the pure random process at one extreme and the pure deterministic process at the other. But the loss of memory is a subtle effect and it is important not to confuse the abrupt cut-off in dependence on the past implied in the transition probabilities with the slower-diminishing autocorrelation in the passage between successive states, which can extend over many transitions.

The mathematics of Markov processes is not as a rule exceptionally difficult but suffers considerably from complications of notation. Because my chief intention is to survey the scope of applications rather than give a detailed exposition, it will be convenient to express the working equations somewhat symbolically, as, for example, in a brief outline of quantum mechanics. Further detail of the mathematical background is readily accessible in several excellent monographs[2-4].

The general Markov process can be represented by the following equation, whose terms must be interpreted somewhat differently according to the case in question

$$\dot{\mathbf{P}}(t) = \mathcal{A}\,\mathbf{P}(t) \tag{1}$$

The left hand side gives the rate of change of the populations of states and this is equated to the effect of a linear operator $\mathcal{A}$ acting on the populations themselves. I shall usually refer to the independent variable t as time, though it may equally well be a spatial parameter such as an index numbering the links in a polymer chain. If the states are discrete (for example, quantum levels, steps on a lattice) $\mathbf{P}(t)$ is a vector

$$\{p_1(t),\ p_2(t),\ \ldots\ p_k(t)\ \ldots\}$$

possibly infinite, the components of which list the probabilities $p_k(t)$ for a sub-system of the ensemble to be in state k at time t. If the process is one in which t varies continuously $\dot{\mathbf{P}}(t)$ is to be taken as the derivative $\mathrm{d}\mathbf{P}/\mathrm{d}t$; if, on the other hand, t varies in fixed intervals it will represent a difference $\Delta\mathbf{P}(t) = \mathbf{P}(t+1) - \mathbf{P}(t)$. The states may, however, be continuously distributed (for example, orientations of links in a freely jointed chain, energy-states of a classical oscillator) and $\mathbf{P}$ then represents an ordinary probability distribution function $P(x,t)$ of the continuous state variable and time.

The nature of the operator $\mathcal{A}$ depends very much on the type of states involved. If these are discrete $\mathcal{A}$ is a matrix the elements of which are related to the transition probabilities K_{ji} for passage between states i and j. (Actually $A_{ji} = K_{ji} - \Sigma_j K_{ji}$.) If the states are continuous $\mathcal{A}$ is an integral operator based on a transition kernel $K(x,y)$ measuring the probability that a system in state x will make a transition to a state in a neighbourhood dy about y in unit time. The dimension of A_{ji} or the range of the kernel K may be finite or infinite as appropriate.

Initial-value Problems

The usual object of calculations on a Markov process is to obtain a full solution of the initial-value problem, that is, expressions for $\mathbf{P}(t)$ at all t subject to some initial distribution $\mathbf{P}(0)$. Sometimes less information will suffice, such as the time-dependence of some average quantity governed by $\mathbf{P}(t)$ or in some cases simply the equilibrium distribution ($\mathbf{P}(\infty)$ to which a given system may tend after

Table 1. SOME ATOMIC AND MOLECULAR MARKOV PROCESSES

Process	States	Linearity assumption	Type*	Desired result	Peculiarities	Reference
Vibrational relaxation	Quantum levels	Dilute system in heat bath	T2 or 4	Relaxation times		5
Vibrational dissociation	,, ,,	,, ,,	T2 or 4	Reaction rate	Passage-time problem	5
Polymer configurations	Orientation of chain links	Short-range excluded vol.	S1 or 3	End-to-end length distrib.		9, 10
Small-system kinetics	No. of molecules reacted	Implicit	T2	Reaction probabilities	Pure death process	12–15
Nucleation kinetics	N-aggregates	Stepwise growth	T2	Growth rate and time-lag	Birth and death process	16–19
Brownian motion	Position or velocity	Dilute system in heat-bath	T4	Evolution, autocorrelation	Gaussian Markov. Classic literature	33–35
Thermalization kinetics	Energy of atom or neutron	,, ,,	T4	Relaxation times. Reaction rates	Continuous spectrum	20
Spin systems	Spin states	Dilute spins in lattice	T2	Response to applied field	Usually 2-state process	44

* I use the following shorthand notation for the four types of spatial (S) and temporal (T) processes. (1) Discrete states/discrete time (or position); (2) discrete states/continuous time; (3) continuous states/discrete time: (4) continuous states/continuous time.

long times. In this, of course, all memory of the initial conditions $\mathbf{P}(0)$ is erased.

In a casual approach to the problem it will be clear that some progress can be made simply by carrying out a systematic "book-keeping" procedure for the flow of sub-systems as time evolves. Symbolically this is equivalent to carrying out the continuous-time solution of equation (1) in the following form

$$\mathbf{P}(t) = \exp(\mathcal{A}t)\mathbf{P}(0) = \{1 + \mathcal{A}t + \tfrac{1}{2}\mathcal{A}^2t^2 \ldots\}\mathbf{P}(0) \qquad (2)$$

Here the powers of the operator $\mathcal{A}^n$ are to be interpreted simply as the operation repeated n times. Although this is a practicable procedure at short times, it rapidly becomes complicated as time increases and is unlikely to give much information on the behaviour of the system as t approaches infinity.

Indeed, if computations were limited to the book-keeping approach, very little of any generality could be said. But the usefulness of the theory of Markov processes as developed during the past 30 years lies in the recognition that the powers of the operator $\mathcal{A}$ or, more straightforwardly, the solution of equation (1), can be expressed in terms of the eigenvalue properties of the simple operator. Thus, if $\mathcal{A}$ has an eigenvalue λ_k and an eigenvector (or eigenfunction) φ_k, that is

$$\mathcal{A}\,\varphi_k = \lambda_k\varphi_k \qquad (3)$$

it is easy to see that a term $\varphi_k \exp(\lambda_k t)$ will be a particular solution of equation (1). If the whole spectrum of λ_k and φ_k for the operator can be determined, then it is usually possible to construct a general solution appropriate to the given initial conditions by a weighted superposition of such terms. I shall illustrate this in later examples.

Several crucial properties follow from the eigenvalue form of the solution. First, it is obvious that, for probabilities to be conserved with increasing time, the operator $\mathcal{A}$ must have eigenvalues λ_k which are all negative or at most zero. ($\mathcal{A}$ is negative semi-definite.) Furthermore, if there are physical requirements that the system should tend to equilibrium as time approaches infinity, then there must be some distribution $\mathbf{P}(\infty)$ with the property that $\dot{\mathbf{P}}(\infty) = \mathcal{A}\mathbf{P}(\infty) = 0$. That is to say, a well formulated operator $\mathcal{A}$ for this case must possess at least one zero eigenvalue $\lambda_0 = 0$ which has the equilibrium distribution $\mathbf{P}(\infty)$ as its corresponding eigenvector. A further simplifying property possessed by most physical systems is the detailed balance condition. This makes it necessary for the flux between any pair of states in equilibrium to be balanced, that is, for discrete states: $p_i(\infty)K_{ji} = p_j(\infty)K_{ij}$. Mathematically, the effect of this is to impose a symmetry property on the operator $\mathcal{A}$ with the very important consequence that all its eigenvalues must be real numbers, as I have anticipated earlier in this article. Thus the oscillatory behaviour associated with the occurrence of complex eigenvalues in systems of equations like (1) is ruled out in most physical examples.

With the Markov process recognized as an eigenvalue problem, many of the properties and techniques familiar in quantum mechanics and the theory of vibrations can be expected to find an application. Indeed, there is considerable scope for perturbation theory, variational calculations, the WKB method, the exploitation of symmetry in relation to the degeneracy of eigenvalues, and so on. Some of these possibilities will be evident in the rest of this article, where I shall attempt to classify both the types of Markov process which arise in physics and chemistry and the particular questions of interest in their solution. The list of processes in Table 1 is by no means comprehensive but should serve to focus the variety of contrasting objectives and assumptions which are possible within the general framework of Markovian theory. I shall only consider the more topically interesting cases in detail.

Vibrational Relaxation and Dissociation

If a collection of diatomic molecules is dispersed in some foreign heat-bath gas with which it is not in thermal equilibrium, transitions between the vibrational energy levels may occur and the evolution of the whole system can be treated as Markovian so long as (*a*) the partial pressure of oscillators is low enough that only collisions with heat bath molecules need be considered and (*b*) the whole gas is sufficiently dilute that there are no dynamical correlations between successive collisions. The transition probabilities K_{ji} for changes of vibrational state must be assigned, for example, by the Landau–Teller model, and will, of course, be a function of heat bath temperature[5,6] (Fig. 1).

These assumptions lead to a transport equation of the following form, in which the constant ω multiplying the second term is simply the oscillator–heat-bath collision number.

$$\mathrm{d}p_i/\mathrm{d}t = \Sigma_j K_{ij} p_j(t) - \omega\, p_i(t) \qquad (4)$$

(that is in matrix terminology: $\mathbf{A} = \mathbf{K} - \mathbf{I}\omega$). The solution for $p_i(t)$, the proportion of oscillators in level i at time t, can then be written

$$p_i(t) = \Sigma_k \alpha_k \varphi_i^{(k)} \exp(\lambda_k t) \qquad (5)$$

where the constants a_k are to be fitted according to the initial distribution $p_i(0)$. The existence of one zero

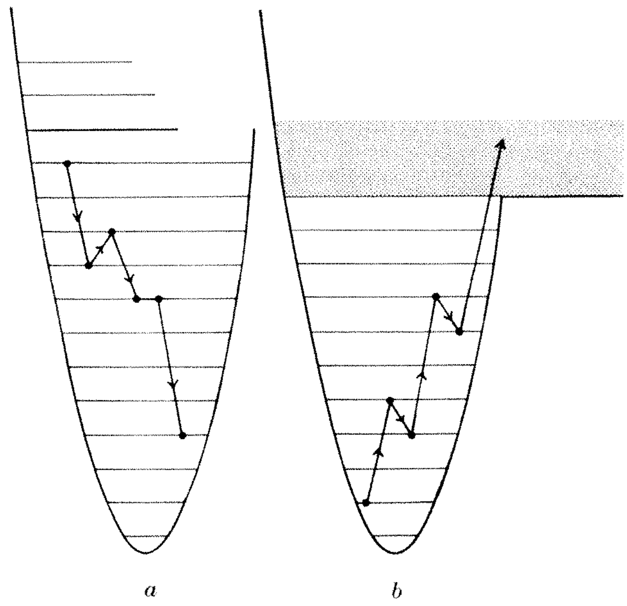

Fig. 1. Markov processes on the vibrational states of a harmonic oscillator. *a*, Simple relaxation; *b*, dissociation at an absorbing barrier.

eigenvalue $\lambda_0 = 0$ guarantees evolution to the equilibrium Boltzmann distribution $p_i(\infty) = \varphi_i^0$. Certain difficulties arise from the essentially infinite character of the set of states, but the eigenvalue analysis can sometimes be carried out in exact form even for the infinite set[5,6].

In the dissociation problem the set of states, and correspondingly the matrix K_{ji}, is truncated at some critical level i^* at which oscillators are supposed to dissociate and become removed from the system. (Statistically i^* represents an absorbing barrier.) Physically it is clear that in time all oscillators will become dissociated (that is, $p_i(\infty) = 0$ for all i); mathematically this comes about because the smallest eigenvalue is perturbed so that now $\lambda_0 \neq 0$. One can attempt to compute, in increasing order of difficulty: (*a*) the mean time taken for oscillators to reach level i^* (the mean first-passage time to reaction); (*b*) the time-dependent concentration $C(t)$ of all unreacted oscillators, and (*c*) the actual time-dependent distribution function $p_i(t)$ for all levels.

If the dissociation limit i^* is relatively high or the temperature of the heat bath relatively low, the absorbing barrier may be treated as a small perturbation on the infinite transition probability matrix K_{ji}. The following results are then obtained. (i) All transients other than $\exp(\lambda_0 t)$ decay relatively fast, leaving an effective Boltzmann distribution throughout the reaction. (ii) The total unreacted population decays by $dC(t)/dt = \lambda_0 C(t)$, that is, the smallest eigenvalue $|\lambda_0|$ becomes the ordinary unimolecular rate-constant. (iii) The mean first-passage time to reaction becomes equal to $-1/\lambda_0$. (iv) The Arrhenius law for the effect of barrier-height and temperature on rate of reaction applies[5,6].

Although attempts have been made to apply a similar scheme to the theory of unimolecular reaction of polyatomic molecules, the difficulty of specifying both the transition probabilities and the states themselves has prevented any very effective solutions being obtained[7,8].

Random Walks and Polymer Configuration

The ordinary random walk in which a jointed chain has its links directed arbitrarily in free space or on a lattice is the simplest model for obtaining the approximate statistics of end-to-end length distribution in a polymer chain. If a set of possible states is taken as the orientations of the *i*th link, the process, as described, is purely random. If, however, it is ruled that a link cannot be reversed along the previous step or intersect an earlier joint, then a Markovian element is introduced with certain transition probabilities becoming zero. In practice it is difficult to allow for interactions further than about three steps back in the chain, but this is sufficient to give some account of the short range contribution to the "excluded-volume" effect (Fig. 2). The eigenvalue analysis of Markov processes on a lattice can be carried out and, as to be expected, there are degeneracies resulting from the symmetries present. Mean end-to-end distances are significantly longer than for the purely random case, though the model is still very far from representing the configuration of a real polymer molecule[9-11]. The problem is not merely one of complexity; some serious conceptual weaknesses in the usual Markovian approach have recently been pointed out[10].

Small System Kinetics

When very few molecules are involved in a chemical reaction, the normal, deterministic rate equations of chemical kinetics cannot apply, fluctuations occur and one can only ask for a probability that, after time t, some number i of an initial total of N molecules remains unreacted. This situation can be treated as a Markov process on N states in which the state i simply corresponds to "i molecules unreacted". For irreversible reactions the behaviour will be that of a "pure death" process with transition probabilities which are zero except in the few cases corresponding to reaction. Thus for the stochastic bimolecular reaction $2A \rightarrow B$ the only finite transition probabilities are of the form $K_{i-2,i} \propto i(i-1)$. A considerable number of articles have given the analysis of such systems[12-15]. In favourable cases the complete distribution function $\{p_k(t)\}$ for the probability of k molecules left unreacted after time t can be obtained; in others various approximations can be made leading to the time-dependence of the moments of this. Usually the mean amount of reaction at time t satisfies a normal, deterministic kinetic equation, but in a stochastic system the law of mass action is only approximately valid[14].

Reactions to which a stochastic approach has been applied include the following: $A \rightarrow B$, $2A \rightarrow B$, $A \rightarrow B \rightarrow C$, $2A \rightarrow B \rightarrow C$, $2A \rightleftharpoons B$ and $E + S \rightarrow C \rightarrow E + P$. The latter will be recognized as the Michaelis–Menten scheme for enzyme kinetics[15]. Because, on general statistical-mechanical grounds, the fluctuations from deterministic behaviour can be expected to disappear as $N^{-\frac{1}{2}}$, it is hardly surprising that no direct measurements of chemical

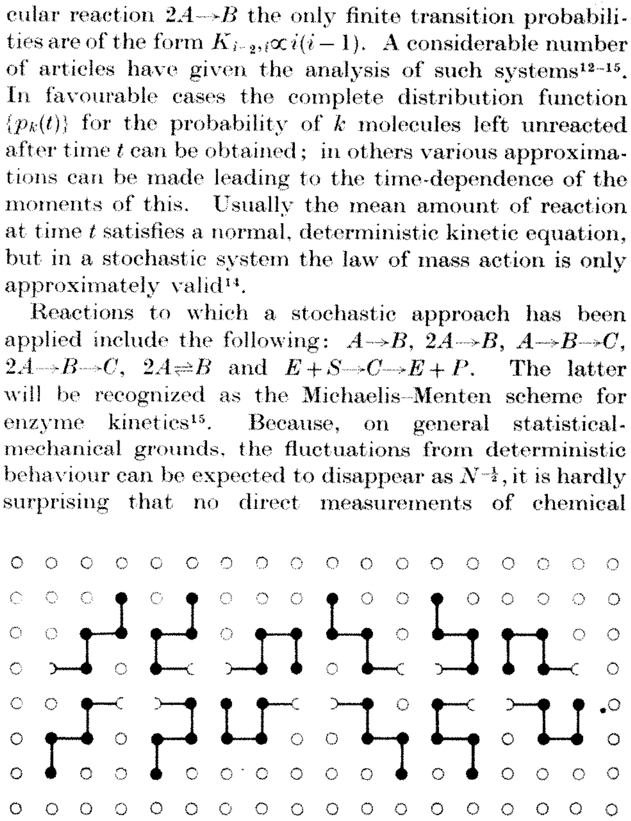

Fig. 2. Markov lattice model for a two-dimensional polymer chain. The twelve basic "states" shown can be combined to generate configurations with short range excluded volume. About half the possible combinations overlap and are given zero transition probability; the rest may be assigned consistent K_{ji} values. (After Montroll[11].)

kinetic fluctuations seem to have been made. (An obviously exceptional case would be the first order decay of a very few atoms of some short lived synthetic radioisotope.) If stochastic effects are ever important in kinetic systems it seems likely that they will be detectable only in specially sensitive situations; for example, the induction period to an explosion, or reactions in certain living systems. Most experimenters will continue to suspect extrinsic errors when they obtain variable kinetic results in several runs.

Nucleation and Droplet Growth

There is good reason to believe that the growth and evaporation of small droplets in a supercooled vapour proceeds by addition or loss of one molecule at a time to the surface of the growing nucleus[16-19]. This makes it possible to treat the kinetics of nucleation as a classic "birth and death" Markov process in which the states are indexed by the number of molecules in the drop and transitions are only allowed between states i and $i \pm 1$. The transition probability matrix is then of tridiagonal form and the equations (1) reduce to a set of differential difference equations. The situation in the growth kinetics of certain polymers such as rubber latex is similar except that the reaction is usually irreversible and the process is of the "pure birth" type with constant growth probabilities[19]. In both cases a "source-term" is introduced for the addition of monomer at a constant rate and in the nucleation problem an absorbing barrier is usually introduced at some critical size i^*. Assuming reasonable models for the pattern of transition probabilities, it is then possible to calculate both the steady state flux through the states and the time-lag in setting this up. In the case of polymerization it is the distribution of chain lengths after time t which is of principal interest because this, unlike the size of nucleating droplets, is an experimentally measurable quantity.

Thermalization Kinetics

Of all the physical Markov processes discussed here the most interesting and mathematically complex is probably that which governs the cooling of a hot atom or subatomic particle in a homogeneous heat bath. A vast literature exists on the subject of neutron thermalization[20] and some of the ideas originating in the field have more recently been applied to the kinetics of "hot atom" reactions and other rate processes in chemical physics[21].

The problem usually considered is to obtain the time-dependent energy distribution, $P(\varepsilon,t)$, of a set of translationally "hot" particles which lose energy by collisions with the moderator. In chemical kinetics the interesting particle is often a hydrogen atom produced by photolysis or electrical discharge, or alternatively a recoil tritium atom. The thermalization process can be taken to be in competition with various possibilities for absorption and chemical reaction.

Under assumptions similar to those described for oscillators, the system can be treated as Markovian and governed by a scattering kernel $K(\varepsilon,\varepsilon')$. This function is known explicitly for a few simple cases such as the hard sphere model[22] and is, in general, a sensitive function of the temperature of the heat bath and the mass ratio for the system and heat bath particles. The transport equation which must be solved is then of the form

$$\frac{\partial P(\varepsilon,t)}{\partial t} = \int_0^\infty K(\varepsilon',\varepsilon)\ P(\varepsilon',t)\,\mathrm{d}\varepsilon' - Z(\varepsilon)\ P(\varepsilon,t) \qquad (6)$$

Although at first sight similar to the continuous form of equation (4), its mathematical properties are radically different on account of the energy dependence in the collision number $Z(\varepsilon)$. This can be shown to give rise to a continuum region in the spectrum of eigenvalues which begins at the point $\lambda^* = Z(0)$ and extends over the whole region where $Z(\varepsilon_\lambda)$ can be equal to λ for some ε_λ. In addition there is usually an infinite set of discrete eigenvalues with a point of accumulation at the continuum threshold λ^*. For the hard sphere case the collision number $Z(\varepsilon)$ increases monotonically from $Z(0)$ so that the spectrum is, as shown in Fig. 3b, a form reminiscent of the hydrogen-atom spectrum in quantum mechanics[23,24]. Several[25-28] quite original mathematical techniques have been devised for the computation of both continuous and discrete parts of the spectrum, but these are very difficult to apply, and it is probably true to say that the physical significance of the continuum eigenfunctions, which are (Schwartz) distributions, is still insufficiently understood.

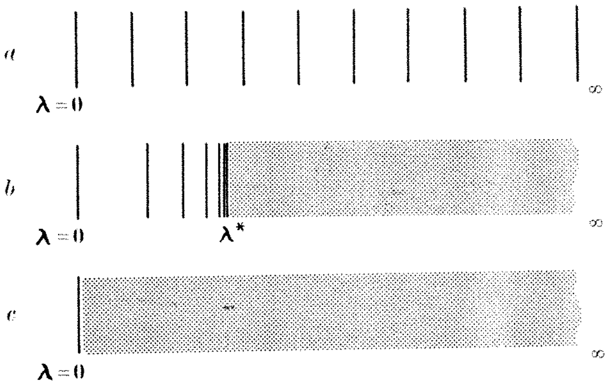

Fig. 3. Eigenvalue spectrum for the thermalization of a test-particle with hard-core interaction. a, The Rayleigh gas. Mass-ratio $\gamma \to 0$. b, The uniform gas ($\gamma = 1$). c, The Lorentz gas ($\gamma \to \infty$). (Schematic only.)

Nevertheless, certain properties of the solutions can be recognized. For example, if the mass of the heat bath particle decreases towards zero, the temperature remaining constant, the zero velocity collision number, for hard interactions at least, must tend to infinity so that the whole eigenvalue spectrum should become discrete in this limit. The resulting spectrum and its corresponding initial value solution $P(\varepsilon,t)$ is then the three-dimensional analogue of Rayleigh's classical exact solution for the one-dimensional gas of infinitely heavy particles; a special case of Brownian motion[29,34]. At the other extreme, when the mass of the system particle becomes very small, $Z(0) \to 0$ and the whole problem becomes dominated by the continuum. This is the case of the "Lorentz gas" undergoing "inverse Brownian motion". It is not surprising that this process is much less well understood than the "Rayleigh gas".

Diffusion Processes

When a Markovian system is dominated by transitions between "close" continuous states or nearest neighbour discrete ones, its mathematics has much in common with that of a diffusion process in ordinary space. With this very considerable restriction, equations of the form (4) and (6) can be approximated by a partial differential equation in a continuous variable and time, which takes the following form[31-34]

$$\partial P(x,t)/\partial t = (\partial/\partial x)\{\alpha_1(x)P(x,t) + \alpha_2(x)\partial P(x,t)/(\partial x)\} \qquad (7)$$

This "Fokker–Planck" equation can be thought of as a generalized diffusion equation with a built-in drift to equilibrium and a state-dependent diffusion constant. The functions $\alpha_1(x)$ and $\alpha_2(x)$ can be derived by systematic procedures from the transition kernel or, in some cases, by a smoothing approximation applied to the tridiagonal matrix for the birth-and-death process. Formally the success of the equation depends on the validity of expressing the integral operator $\mathscr{J}$ as a differential operator of infinite order, and then throwing away all but first and second-order terms—a procedure involving more sleight of hand than mathematical rigour.

A system the evolution of which is described by equation (7) is said to undergo a Gaussian Markov process and has the important property that the "autocorrelation" between successive states decays exponentially[34]. Although in physics the Fokker–Planck equation is usually thought of in the context of Brownian motion, it is also a useful approximation in the treatment of several of the processes already mentioned—nucleation, polymerization and thermalization in the Rayleigh and Lorentz limits. Other applications worth mentioning are the Kramers theory of unimolecular reactions as a Brownian motion in phase space[37], and the "Alkemade diode" problem where it describes the fluctuation of charge in a stochastic R–C circuit[38].

There are, however, serious pitfalls in the use of diffusion approximations. The Fokker–Planck equation will always tend to falsify the higher eigenvalues of the spectrum and can give no account of any continuum region; this must always lead to significant errors at short times and with sharply peaked distributions. It has recently been possible to demonstrate these discrepancies and map out the region of validity of the F–P equation for the hard sphere gas by comparing eigenvalue spectra obtained from the differential and integral equations[39].

Deeper Role of Markofficity

In summarizing these physical realizations of the Markov process I have concentrated on exposing their variety at the expense of mathematical subtleties. Rather deliberately I have avoided emphasis on Brownian motion and the Gaussian Markov process which has so dominated the statistical physics literature in past decades. Though the importance of the Brownian motion process must not be underestimated, the tendency to treat it as a prototype for all physical stochastic processes has been to some extent unfortunate, the result, it would seem, of a long standing reluctance to face the complexities of an integral equation so long as the problem could be forced into a more familiar, if misleading, differential form. The breaking of this habit, within the physical sciences, is largely to the credit of the nuclear reactor theorist whose special Markov processes are of a practical importance that need hardly be emphasized. When fully translated from the rather peculiar language of the subject, the mathematical fall-out from applied neutron scattering and transport theory may prove to be one of the most impressive examples of pure science being led by technology.

The cases I have considered are all rather specific physical or chemical systems; it would be wrong not to mention the deeper aspects of the Markovian property which seem to lie close to the foundations of statistical mechanics and quantum theory and are perhaps inseparable from the idea of irreversibility in nature. It seems widely accepted that the paradoxes of time-reversal asymmetry may be described, if not actually explained, in terms of a Markovian "forgetting" of past history in a large system, though it is not clear how this comes about or whether it must necessarily have a quantum mechanical origin. The Kac–Ehrenfest "dog-flea" model of an irreversible process is a Markovian thought experiment compellingly suggestive of some central role[41,42].

At the same time considerable efforts are in hand to connect the non-deterministic aspects of quantum equations of motion with some kind of Markovian or more general stochastic process[43]. A certain difference of opinion seems to exist as to whether such a reconciliation, even if possible, would be of deep significance, or merely a superficial parallel. If the former view should come to be justified, the Markov process might conceivably attain a central importance in the scheme of natural laws which would dwarf altogether the special applications considered here.

The citations in the reference list are not intended to give a full account of work on the relevant topic or necessarily to indicate priority. Where possible I have quoted an early, key paper together with a more recent one containing a useful bibliography.

Gene Order of RNA Bacteriophage M12

In vitro translation of M12 RNA nascent strands, isolated from the M12 replicative intermediate, revealed the gene order: 5′–A-protein–coat protein–replicase–3′.

THE genomes of RNA phages serve both as templates for phage specific RNA replication and as messengers for protein synthesis. These genomes (mol. wt. $1\cdot1\times10^6$) contain three complementation groups which code for the three gene products: coat protein, maturation (A) protein and RNA replicase[1–4]. During phage reproduction, coat protein is made in much greater quantities than the other two phage proteins[5]. This led to the suggestion that the coat protein gene might be located nearest to the 5′ end of the phage RNA molecule, a hypothesis derived from polarity studies carried out with polycistronic bacterial messengers. Initial results were consistent with this idea and, furthermore, suggested that the replicase gene was nearest to the 3′ end of the molecule[6–8].

We present here the complete gene order of RNA bacteriophage M12, obtained by studying the translation of nascent RNA strands *in vitro*. The replication of phage RNA occurs linearly from the 5′ to the 3′ end of the molecule. As the nascent strands grow, they should first be translated into the protein whose gene is nearest to the 5′ end. Larger strands should then contain information for the second and, finally, for the third phage specific protein.

Six fractions of nascent strands, designated A to F, were isolated from the replicative intermediate of the RNA bacteriophage M12 and purified according to their molecular weights (Table 1). By using these nascent strands as *in vitro* messengers we have established the following gene order: 5′–A-protein–coat protein–replicase–3′.

Translation of Nascent M12 RNA Strands

Three criteria were used to identify the protein products synthesized in an *Escherichia coli in vitro* system under the direction of nascent strands: coelectrophoresis of the products on polyacrylamide gels with the phage specific proteins synthesized both *in vivo* and *in vitro* under the direction of phage M12 RNA (Figs. 1*i* and *k*); the absence of histidine from the phage coat protein[13] (Fig. 1*k*); and the repression of replicase synthesis but not of coat protein synthesis by native coat protein[6,7,14–17] (Fig. 1*k*).

Using the nascent M12 strands as messengers, the shortest RNA fragment able to direct protein synthesis was fraction C (9S) (Figs. 1*a* and 1*b*). Apparently, nascent strands A and B (1·4S and 3·5S respectively) are too small to stimulate the synthesis of a trichloroacetic acid precipitable product. Although nascent strand C was primarily translated into many unidentifiable short peptides, it did direct the formation of some larger protein material. This larger material cannot be coat protein, for it has a higher molecular weight and contains histidine. It must therefore be a fragment of incomplete replicase or A-protein.

Nascent strand D (14S) stimulates the synthesis of larger peptides than does nascent strand C, some of which migrate in the region of the A-protein (Figs. 1*c* and 1*d*). No distinct A-protein or replicase peak can be detected, however. Some protein material which migrates like coat protein can also be observed. Two facts, however, indicate that this material cannot be coat protein: it has a high, constant histidine : leucine ratio, whereas coat protein does not contain histidine; and its synthesis can be repressed by M12 coat protein (Fig. 1*c*).

Nascent strand E (19S) is the shortest RNA fraction to stimulate the synthesis of a clear coat protein peak, identified by its gel position and its lack of histidine (Figs. 1*e* and 1*f*). Some of the histidine containing material made from this strand has a higher molecular weight than that found under the direction of nascent strand D, but still only a minute peak can be observed in the region of the replicase protein. Beginning with nascent strand F (25S), a sharp histidine containing peak can first be observed in the position of the replicase (Figs. 1*g* and 1*h*). The ratios of replicase to coat protein synthesized under the direction of nascent strand E, strand F and phage M12 RNA increase dramatically with the size of the RNA (Table 2). These results show that the coat protein gene immediately precedes the gene for M12 replicase, which agrees with results obtained from sequence studies carried out with phage R17[24,25]. Furthermore, because the informational content of strand F is almost as great as that of intact phage RNA, the replicase gene must be localized very near to the 3′ end. Thus the histidine containing material appearing before the coat protein (nascent strands C and D in Figs. 1*a*–*d*) must have been

Table 1. PHYSICAL PROPERTIES OF NASCENT STRANDS ISOLATED FROM THE REPLICATIVE INTERMEDIATE OF BACTERIOPHAGE M12

Nascent RNA strand	Sedimentation value	Approximate mol. wt.	Average informational content (amino-acids)
A	1·4S	5×10^3	5
B	3·5S	$2\cdot5\times10^4$	25
C	9S	$1\cdot5\times10^5$	150
D	14S	$3\cdot3\times10^5$	330
E	19S	$5\cdot7\times10^5$	570
F	25S	$9\cdot5\times10^5$	950
Phage M12 RNA	27S	$1\cdot1\times10^6$	1,100

The replicative intermediate (RI) of M12 RNA was isolated as described by Francke and Hofschneider[9]. The nascent strands were obtained from the RI by heat denaturation and thereafter were separated by zonal centrifugation ('B XIV' rotor, 47,000 r.p.m., 4 h, 20° C) in a 10–30 per cent sucrose gradient in 0·1 M NaCl, 0·05 M Tris-HCl (*p*H 6·9), 0·001 M EDTA, 0·1 per cent sodium dodecyl sulphate (SDS). Six fractions of nascent RNA strands were obtained and further purified by conventional band sedimentation. Finally, the peak fractions were concentrated by ethanol precipitation. The sedimentation constant of nascent strand D was determined by co-sedimenting a sample with infectious M12 RNA. The sedimentation constants of the fractions A, B, C, E and F were calculated[12] from this value. The approximate molecular weights of these nascent RNA strands, relative to that of complete phage RNA, were determined by the method of Studier for single-stranded DNA[10]. Further details will be given elsewhere. No random fragmentation of RNA nascent strands could be detected throughout the preparation procedure. The specific infectivity (p.f.u./$A_{260\text{ nm}}$) of the purified and denatured RI was 0·18 with respect to single-stranded plus strands. This value is close to the theoretical value of 0·5 for completely double-stranded replicative form phage RNA. The specific infectivity of the nascent strand material remained practically unchanged throughout the subsequent purification steps. When the $A_{260\text{ nm}}$ values of the six fractions of nascent strands after zonal centrifugation were plotted as a function of their molecular weights as given in Table 1, either before or after the final band sedimentation, a linear correlation between $A_{260\text{ nm}}$ and molecular weight was found for fractions A to E. The average length of the nascent strands was determined as 0·3 of the complete phage RNA. This value agrees with that described by Robertson and Zinder[11], who checked the integrity of their material by another method. In accordance with their result, the molar quantity of fraction F was less than that found for the other nascent strand fractions.

Table 2. RATIOS OF M12 REPLICASE/COAT PROTEIN SYNTHESIZED *in vitro* UNDER DIRECTION OF NASCENT M12 RNA STRANDS

Nascent RNA strand	Replicase/coat protein
E	$< 10^{-2}$
F	6×10^{-2}
Phage M12 RNA	6×10^{-1}

Ratios were determined from the total radioactivity (c.p.m.) of ^{3}H-leucine incorporated into M12 replicase or coat protein, respectively, as measured from the polyacrylamide gel patterns shown in Figs. 1*e*, *g* and *i*.

---

[*] Present address: Molecular Biology Institute, Department of Zoology, University of California, Los Angeles.

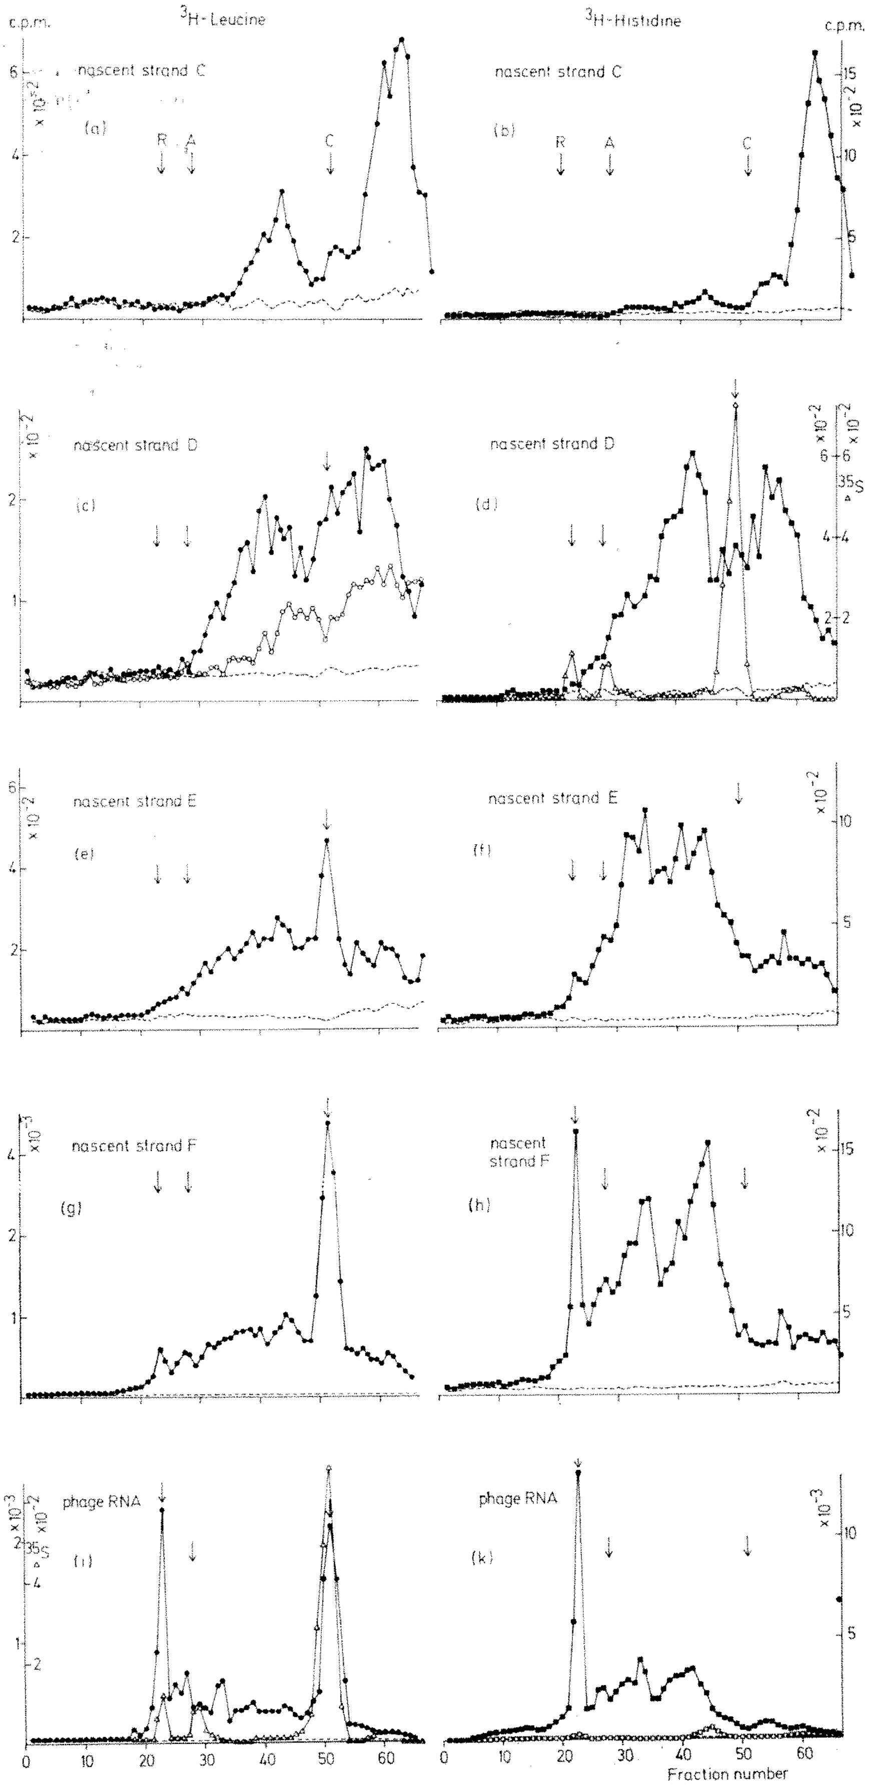

Fig. 1. Polyacrylamide gel electrophoresis of proteins in the cell-free extract of *E. coli* in the presence or absence of nascent M12 RNA strands. ●—●, ^{3}H-leucine labelled proteins synthesized under direction of nascent M12 RNA strands (*a*), (*c*), (*e*), (*g*) and phage M12 RNA (*i*). ■—■, ^{3}H-histidine labelled proteins synthesized under direction of nascent M12 RNA strands (*b*), (*d*), (*f*), (*h*) and phage M12 RNA (*k*). - - -, ^{3}H-labelled protein synthesized in the absence of exogenous RNA. ○—○ and □—□, ^{3}H-labelled proteins synthesized in presence of M12 coat protein (*c*), (*k*). △—△, ^{35}S-labelled proteins synthesized in actinomycin C_3 treated cells infected with the phage M12 and used as markers in (*d*) and (*i*). The radioactivity from control samples has been subtracted. Arrows at R, A and C refer to locations of complete replicase, *A*-protein and coat protein, respectively. The electrophoresis pattern of the proteins isolated from M12 phage, known to contain only *A*-protein and coat protein[18], can be superimposed on their respective peaks (unpublished results). Phage M12 RNA and nascent RNA strands, used to direct the cell-free protein synthesis (10–25 μg/assay tube, 60 μl. total incubation volume), were isolated from purified phage[23] and M12 replicative intermediate (Table 1), respectively. The M12 coat protein was isolated from purified phage with 66 per cent acetic acid. The centrifuged supernatant was dialysed overnight against 0·001 M acetic acid before being used in repression studies[14]. The cell-free system of *E. coli* strain AB301 (λ), met$^-$ and ribonuclease I$^-$, was prepared as described[19], but before being stored in liquid nitrogen the preincubated extract (30 min at 37° C) was dialysed for 5 h at 2° C against three changes of 0·05 M Tris-HCl (*p*H 7·8), 0·01 M magnesium acetate, 0·06 M NH_4Cl, 0·006 M 2-mercaptoethanol. The reaction mixture contained the components described by Capecchi[20]. Incubations (30 min at 37° C) were performed in the presence of ^{3}H-leucine (10 nmole/ml., 5 Ci/mmole) and ^{3}H-histidine (2 nmole/ml., 40 Ci/mmole). Where indicated, coat protein was added to the RNA before incubation (molar ratio of coat protein/RNA, approximately 40). The reaction was terminated by the addition of one-fourth volume of 0·25 M Tris-HCl buffer, *p*H 7·8, containing 5 per cent SDS, 0·25 M EDTA and 0·7 M 2-mercaptoethanol and vigorous shaking. An equal volume of phenol, saturated with this buffer, was added. The mixture was shaken for 5 min at room temperature and centrifuged for 10 min at 10,000 r.p.m. The phenol layer was removed and the extraction procedure was repeated. To precipitate the proteins, two volumes of acetone containing 0·1 M acetic acid were added to the combined phenol layers which were left to stand for 30 min in an ice bath. The precipitate was centrifuged (10 min at 10,000 r.p.m.), washed once with 5 ml. ether–ethanol (1 : 1) and once with 5 ml. ether, dried and then dissolved in a small volume of 0·01 M sodium phosphate (*p*H 7·2), containing 0·1 per cent SDS, 0·14 M 2-mercaptoethanol and 4 M urea. This solution was dialysed for 24 h against 500 volumes of the same buffer. The dialysing solution was changed twice. To 160 μl. of the dialysed solution, 40 μl. glycerol and 1 μl. 0·2 per cent bromophenol blue were added. This was layered onto 10 per cent polyacrylamide diacrylate gels (length 6·5 cm, diameter 0·6 cm), prepared in the presence of 4 M urea according to Viñuela *et al.*[3]. The electrophoresis buffer was 0·1 M phosphate (*p*H 7·2), containing 0·1 per cent SDS, 0·14 M 2-mercaptoethanol and 4 M urea. Electrophoresis was at room temperature for 12 h, 5 mA/gel. When the marker had reached the bottom of the tube the gels were removed and sliced, without freezing, into 1 mm sections. The slices were placed in scintillation vials and dissolved, with shaking, overnight at 37° C in 1 ml. of a solution consisting of 10 per cent piperidine and 10 per cent 'Hyamine 10X'. 15 ml. Kinard's scintillation solution[21] was added to each vial and the samples were counted in a Packard 'Tri-Carb' liquid scintillation counter. The procedure described by Oeschger and Nathans[5] for the preparation of phage specific proteins from infected cells was followed. Cells were grown in 'M9' medium[22] containing $MgCl_2$ in place of $MgSO_4$. $^{35}SO_4$ was added to label the proteins and actinomycin C_3 was used instead of actinomycin D (final concentration: 6 μg/ml.). 40 min after infection the cells were lysed by the method described by Fromageot and Zinder[23]. The proteins were isolated in essentially the same manner as the *in vitro* products.

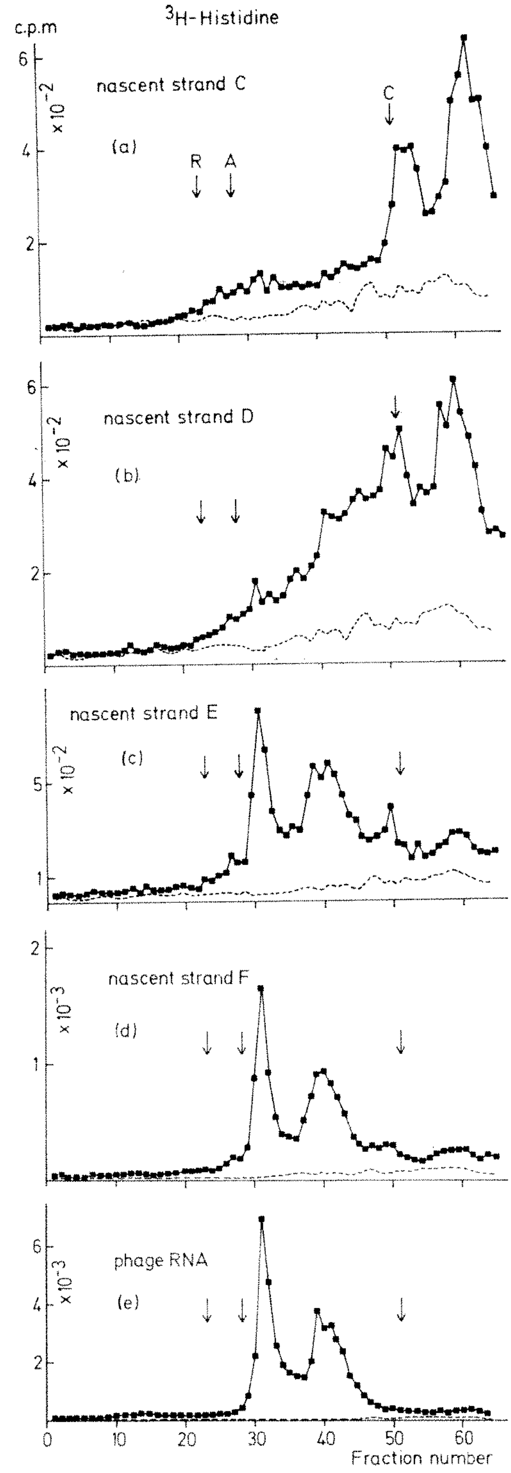

Fig. 2. Polyacrylamide gel electrophoresis of proteins made in the cell-free extract of *B. stearothermophilus* in the presence and absence of nascent M12 RNA strands. ■—■, ^{3}H-histidine labelled proteins synthesized under the direction of nascent M12 RNA strands (*a*), (*b*), (*c*), (*d*) and phage M12 RNA (*e*). - - -, ^{3}H-histidine labelled proteins synthesized in the absence of exogenous RNA. Arrows marked R, A and C refer to locations of complete replicase, *A*-protein and coat protein, respectively. *B. stearothermophilus* strain NU10 (a gift of Dr W. Zillig) was grown at 65° C in the medium described by Friedman and Weinstein[27]. The preparation of the cell-free system and the composition of the incubation mixture were as described in Fig. 1. All incubations were at 55° C for 20 min in the presence of ^{3}H-histidine (2 nmole/ml., 40 Ci/mmole). No extra tRNA was included. The method of protein isolation and the procedure of polyacrylamide gel electrophoresis are described in the legend to Fig. 1.

synthesized under the direction of the *A*-protein gene. Consequently, that gene must be located near the 5′ end and be followed by the coat protein gene and, finally, by the replicase gene. Although there are indications that complete *A*-protein is made in the *E. coli* system[34], no sharp *A*-protein peak can be demonstrated in the gel patterns, so that no direct evidence for the localization of the *A*-protein gene can be derived from these experiments.

In a cell-free system derived from *Bacillus stearothermophilus*, synthesis of only the phage *A*-protein is initiated[25,26]. If the gene order we postulate is correct, the small nascent strands (C and D) should initiate protein synthesis in this system. Fig. 2 shows that strand C stimulates some protein synthesis and must therefore contain the initiation site of the *A*-protein gene. Furthermore, strand D directs the synthesis of material with a higher molecular weight than that stimulated by strand C, and the *A*-protein gene is essentially complete in strand E, for its translational product is almost identical to that directed by complete phage RNA. When equal molar quantities of strands E and F are used, F directs the synthesis of about twice as much protein as E in this system. The difference in coat protein synthesis by equal molar quantities of these strands in the *E. coli* system (Figs. 1*c* and 1*d*) is, however, more than ten-fold. Thus strand E synthesizes relatively much more *A*-protein than coat protein, confirming that the *A*-protein gene precedes the coat protein gene.

It should be noted that even the largest peptide synthesized in the *B. stearothermophilus* system migrates slightly faster during gel electrophoresis than *A*-protein synthesized *in vivo*. This indicates that *A*-protein synthesis is somehow interrupted in this system. Comparable results were found by Lodish[26], who has shown that, although all tryptic peptides of *A*-protein labelled with methionine are made in this cell-free system, much less of the tryptic peptide located nearest to the C-terminus of the molecule is synthesized relative to the peptide fragments found nearer the N-terminus.

The protein products synthesized *in vitro* by the nascent strands (Figs. 1 and 2) can be directly correlated with their average informational contents (see Table 1), as shown in the map of Fig. 3. The finding that nascent strands A and B, containing approximately fifteen and seventy-five nucleotides respectively, do not stimulate protein synthesis agrees with the report that the first initiation codon is not located within the first sixty nucleotides nearest to the 5′ end[25,28] of the RNA molecule. The hypothesis that a fourth gene[29,30] exists in phage RNA is not supported by our results—there would be insufficient space for a gene of usual size. We cannot, however, exclude the possibility that the nucleotide sequences between the known genes or the base sequences at the 5′ and 3′ ends of the RNA molecule are involved in the synthesis of small peptides. No termination codon has been detected within the sequence of nucleotides at the 3′ end studied so far[28].

In view of biochemical similarities we conclude, finally, that the gene order we describe here also applies to the other members of the f2 group to which M12 is serologically related[31,32].

Implication of the Gene Sequence for Regulation

As can be seen in Fig. 1*i* and *k*, the phage *A*-protein gene is much less frequently translated than the coat protein gene. In the light of the gene order, this difference in efficiency of translation can no longer be explained by polarity mechanisms as previously suggested[6-8]. Apparently—at least for polycistronic phage RNA messenger—other regulatory mechanisms must be postulated, for example, initiation sites of different specificities[25].

Coat protein represses the translation of the phage replicase gene. In addition (Fig. 1*c*), the synthesis of complete *A*-protein can also be repressed, which agrees

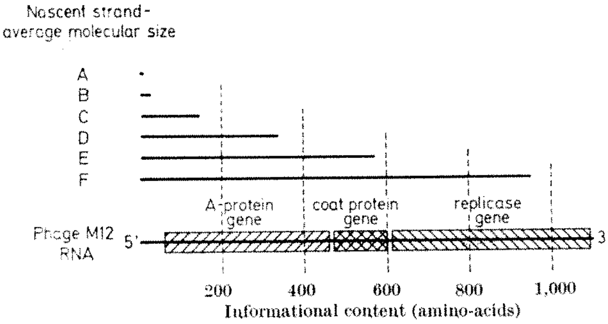

Fig. 3. Linear model of M12 RNA, showing the gene order, the approximate gene size, and the informational content of the complete M12 RNA molecule in relation to the incomplete M12 nascent strands. The informational contents of the nascent strands and of complete phage RNA are given in Table 1. Molecular weights—and amino-acid contents—of *A*-protein, coat protein and replicase were estimated from the results of polyacrylamide gel analyses (unpublished). The beginning of the *A*-protein gene is not made to coincide with the 5′ end of the phage RNA molecule, for it is known that nascent strands A and B do not stimulate protein synthesis and no initiation site occurs within the first sixty nucleotides from the 5′ end[25,28]. The reason for the gap shown between the coat protein and replicase genes is based on the finding that the termination codon for coat protein and the initiation codon for the replicase are not closely linked[24,25]. Similarly, a discontinuity is assumed to occur between the *A*-protein gene and the coat protein gene. As described in the text, the end of the replicase gene must be near to the 3′ end of the RNA molecule. Because no termination codon has so far been found in the nucleotides located near the 3′ end of this molecule[28], the end of the replicase gene is not placed directly at the terminus of the RNA genome.

with the findings of most other investigators[14-17], although not with those of Lodish and Robertson[34]. But because it has also been shown[6,7] that the initiation of *A*-protein synthesis cannot be repressed, we conclude, tentatively, that coat protein represses only a part of the *A*-protein gene. This would also explain why a small but constant histidine containing peptide is synthesized in the *E. coli* cell-free system under the direction of repressed M12 RNA (Fig. 1*k*). Because coat protein probably represses two phage genes which are separated by a third gene, these coat protein molecules must therefore act at two or more different sites, either by binding directly to specific sites or by modifying the secondary structure of the RNA molecule.

We thank Drs W. Fiers and R. Gesteland for discussion, Professor A. Butenandt for his interest, and Miss Eva Zehelein for her assistance. The work was supported by grants from Euratom and Niels Stensen Stichting (to R. N. H. K.), from the Jane Coffin Childs Memorial Fund for Medical Research (to R. W.) and from the Deutsche Forschungsgemeinschaft (to P. H. H.).

Cytoplasmic Methionine Transfer RNAs from Eukaryotes

by
A. E. SMITH
K. A. MARCKER
MRC Laboratory of Molecular Biology,
Hills Road, Cambridge

Eukaryotic cells contain two species of methionine accepting tRNA. One of these (Met-tRNA$_{F*}$) only incorporates methionine into N-terminal positions of polypeptides whereas the other (Met-tRNA$_{M*}$) donates methionine into internal positions. It is suggested that tRNA$_{F*}^{Met}$ is an initiator tRNA on 80S ribosomes.

TRANSFER RNA from bacteria contains two methionine accepting species tRNA$_F^{Met}$ and tRNA$_M^{Met}$[1]. Methionine attached to tRNA$_F^{Met}$ can be enzymatically formylated to give formylmethionyl tRNA$_F$ (fMet-tRNA$_F$), while methionyl tRNA$_M$ (Met-tRNA$_M$) does not accept formyl groups[2]. fMet-tRNA$_F$ is the chain initiator on the 70S ribosomes found in all prokaryotes and prokaryotic-type organelles (that is, chloroplasts and mitochondria)[3]. A distinguishing feature of the initiator tRNA is that Met-tRNA$_F$, even when not formylated, donates methionine exclusively into N-terminal positions of newly synthesized proteins; whereas Met-tRNA$_M$, in common with all other amino-acyl-tRNAs, donates its amino-acid into internal positions[4]. The failure of Met-tRNA$_F$ to incorporate methionine into internal positions is probably a result of its inability to form a complex with transfer factor T and GTP[5]. This, together with other unusual properties such as unique codon–anticodon recognition[1,6], and the specific interaction with the initiation factors[7], implies that the structure of tRNA$_F^{Met}$ has been specially adapted for its role as the initiator tRNA.

The mechanism of initiation on 80S type ribosomes is unknown. There are no confirmed reports of fMet-tRNA in the cytoplasm of eukaryotes. Cytoplasmic tRNA from guinea-pig liver[8] and yeast[9], however, contains two major methionine accepting tRNAs. As we have indicated, such systems do not contain transformylase activity, but one of the two Met-tRNAs can be formylated by *E. coli* transformylase[8,9]. Further experiments have revealed that cytoplasmic fMet-tRNA from such systems functions as a chain initiator with the same requirements and properties as *E. coli* fMet-tRNA$_F$ in the *E. coli* cell-free system[3,8,9]. Thus many of the unique structural features of *E. coli* tRNA$_F^{Met}$ have been retained in one of the

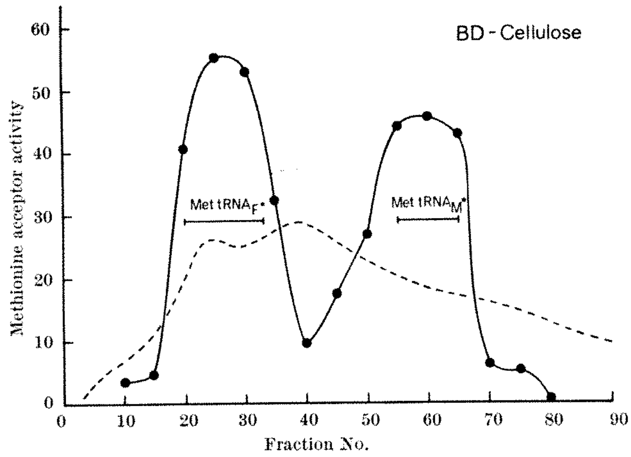

Fig. 1. Chromatography of partially purified tRNA$^{\mathrm{Met}}$ from ascites tumour cells on benzoylated DEAE cellulose. Approximately 100 A_{260} units of partially purified tRNA$^{\mathrm{Met}}$ from ascites tumour cells were applied to a 9 × 1 cm column of BD cellulose. The column was developed by a linear gradient formed from 200 ml. of 0·45 M NaCl, 0·01 M $MgCl_2$ and 0·001 M β-mercaptoethanol and 200 ml. of a similar solution containing 0·9 M NaCl. The flow rate was 10 ml./h and 2 ml. fractions were collected. ●—●, Methionine acceptor activity plotted in arbitrary units; - - - -, A_{260}.

Met-RNAs from yeast and guinea-pig liver, although the primary sequences of *E. coli* tRNA$^{\mathrm{Met}}_{\mathrm{F}}$ and the corresponding species in these systems are different[9,10].

We report here the separation of two methionine accepting tRNAs (tRNA$^{\mathrm{Met}}_{\mathrm{F^*}}$ and tRNA$^{\mathrm{Met}}_{\mathrm{M^*}}$) from mouse ascites tumour cells, mouse liver and yeast. tRNA$^{\mathrm{Met}}_{\mathrm{F^*}}$ is defined as that species which can be formylated by *E. coli* transformylase. We further demonstrate that Met-tRNA$_{\mathrm{F}}$* incorporates methionine exclusively into N-terminal positions of newly synthesized polypeptides in a cell-free system derived from mouse ascites tumour cells. Similar experiments with Met-tRNA$_{\mathrm{M}}$* revealed that methionine from this species is incorporated into internal positions only. This strongly suggests that mammalian transfer factor T-I discriminates against cytoplasmic Met-tRNA$_{\mathrm{F}}$*, just as bacterial transfer factor T discriminates against Met-tRNA$_{\mathrm{F}}$. Furthermore, the incorporation of methionine from Met-tRNA$_{\mathrm{F}}$* only into N-terminal positions indicates a special interaction between this tRNA and 80S ribosomes similar to that between 70S type ribosomes and bacterial tRNA$^{\mathrm{Met}}_{\mathrm{F}}$. These results are therefore taken to imply that Met-tRNA$_{\mathrm{F}}$* is a chain initiator on 80S type ribosomes, though not necessarily the only one.

Separation of Met-tRNAs

Krebs IIA mouse ascites tumour cells were propagated in male Schofields strain mice as previously described[11]. Pre-incubated S30 was made from washed cells by the method of M. B. Mathews and A. Korner (manuscript in preparation). Ribosomes were pelleted from the S30 by centrifugation at 150,000*g* for 90 min. The supernatant (S150) was then passed through a column of 'Sephadex *G*25' equilibrated with buffer *A* (120 mM KCl, 20 mM Tris HCl *p*H 7·5, 5 mM MgOAc, 6 mM β-mercaptoethanol) and stored in aliquots in liquid nitrogen. Ribosomes were re-pelleted through 1 M sucrose in buffer *A*, resuspended in buffer *A* and stored in liquid nitrogen. The preparation of encephalomyocarditis (EMC) virus and viral RNA has been described[11]. Amino-acyl-tRNA synthetases were prepared from the post ribosomal supernatants of mouse ascites cells, mouse liver and yeast by 40–70 per cent ammonium sulphate fractionation; when necessary endogenous tRNA was removed by passage through DEAE cellulose columns. Transfer RNA was isolated from Krebs IIA mouse ascites tumour cells and mouse liver, by repeated extraction of whole cells and liver with water-saturated phenol, followed by ethanol precipitation of the aqueous phase. Yeast tRNA was obtained commercially. The crude tRNAs were chromatographed on DEAE 'Sephadex'[9,12]. This gave little or no fractionation of the Met-tRNAs but led to an approximately four-fold increase in specific activity. The Met-tRNAs were separated by further chromatography on benzoylated DEAE (BD) cellulose. Fig. 1 shows the elution profile of ascites cell Met-tRNAs previously purified on DEAE 'Sephadex', on BD cellulose. Clearly two methionine accepting species are separated on this column. Identical elution profiles and separation of Met-tRNAs were obtained by chromatography of partially purified Met-tRNA from mouse liver and yeast.

Fig. 2 shows an autoradiograph of an ionogram of a ribonuclease T_1 digest of the two Met-tRNAs charged with ^{35}S-methionine by the homologous amino-acyl-tRNA synthetase in the presence and absence of *E. coli* transformylase. The two Met-tRNAs have different nucleotide sequences near the amino-acid acceptor end and only the methionyl-oligonucleotide from Met-tRNA$_{\mathrm{F}}$* is converted to the formyl-derivative when charged in the presence of *E. coli* transformylase. Similar digestion patterns were obtained for the separated Met-tRNAs from mouse liver and yeast. In all cases the degree of cross-contamination was less than 5 per cent. The terminal sequence of yeast Met-tRNA$_{\mathrm{F}}$* is CUACCA-Met[9]. Because the corresponding

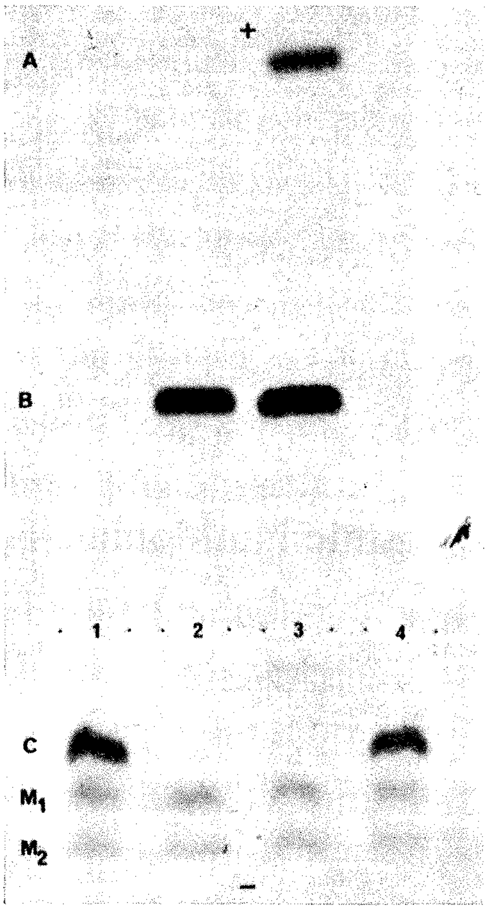

Fig. 2. Autoradiograph of an ionogram of T_1 ribonuclease digests of separated Met-tRNAs from ascites cells. Separated Met-tRNAs from ascites tumour cells were charged with ^{35}S-methionine by crude homologous aminoacyl-tRNA synthetases in the presence and absence of crude *E. coli* supernatant and formyl donor. After re-isolation the charged tRNAs were digested with T_1 ribonuclease (1 : 50)[2]. After 20 min at 37° C the samples were applied to Whatman 3 *MM* paper and electrophoresed at *p*H 3·5 for 3 h. 1, Digest of ^{35}S-Met-tRNA$_{\mathrm{M}}$* charged by ascites enzyme only; 2, digest of ^{35}S-Met-tRNA$_{\mathrm{F}}$* charged as for 1; 3, digest of ^{35}S-Met-tRNA$_{\mathrm{F}}$* charged by ascites enzyme in the presence of *E. coli* supernatant and formyl donor; 4, digest of ^{35}S-Met-tRNA$_{\mathrm{M}}$* charged as for 3. *A*, A formyl methionine containing oligonucleotide; *B* and *C*, methionine containing oligonucleotides. M_1 and M_2, methionine sulphoxide and methionine respectively.

methionyl-oligonucleotides from ascites cell and mouse liver Met-tRNA$_F$*s have mobilities identical to the yeast oligonucleotide it is probable that the terminal sequence of these tRNAs is also CUACCA$_{OH}$. It is interesting that the formyl methionyl-oligonucleotide obtained from rat liver mitochondrial fMet-tRNA by ribonuclease T$_1$ digestion also has the same mobility as that obtained from enzymatically formylated Met-tRNA$_F$* from the corresponding cytoplasm.

Although separation was not attempted we have further found that rat liver and rabbit reticulocyte tRNA contain a methionine tRNA that can be formylated by *E. coli* transformylase. A similar result has also been reported for tRNA isolated from the protozoan, crithidia (G. Cross, personal communication). These findings therefore indicate that many, perhaps all, eukaryotic cells contain a cytoplasmic species of Met-tRNA that is recognized by *E. coli* transformylase.

Methionine Incorporation in Cell-free Systems

For incorporation studies using the separated Met-tRNA species we used a cell-free system prepared from mouse ascites tumour cells. All experiments were carried out at 5 mM Mg^{2+} concentration, which is the optimum for endogenous and EMC RNA translation[13]. Table 1 records the results obtained using synthetic polymers and EMC RNA. Met-tRNA$_M$* donates methionine into polypeptides in response to random poly-AUG better than does Met-tRNA$_F$* whereas the reverse is the case for poly-UG. This is identical to the results obtained previously with similar polymers in the *E. coli* cell-free system using *E. coli* Met-tRNA$_F$ and Met-tRNA$_M$[1]. In the latter case Met-RNA$_F$ incorporated methionine into N-terminal positions only while Met-tRNA$_M$ incorporated methionine into internal positions. Accordingly, end group determinations on the polypeptides synthesized in the mammalian cell-free system were carried out by the Edman procedure[14]. From the results shown in Table 2 it is evident that methionine from Met-tRNA$_F$* is N-terminal while that from Met-tRNA$_M$* is internal. This result was further confirmed using the blocked polymers AUG(U)$_n$ and GUG(U)$_n$ (where n is about 30). As Table 1 shows, only Met-tRNA$_F$* donates methionine in response to these polymers, Met-tRNA$_M$* being totally inactive in these conditions.

Table 1. INCORPORATION OF ^{35}S-METHIONINE FROM SEPARATED Met-tRNAs FROM ASCITES TUMOUR CELLS

	*p*Moles of ^{35}S methionine incorporated from (1) ^{35}S-Met-tRNA$_F$*	(2) ^{35}S-Met-tRNA$_M$*
(*A*) Additions		
None	0·02	0·11
30 μg of poly-AUG (1 : 2·5 : 1)	0·26	0·60
25 μg of poly-UG (1 : 1)	0·84	0·31
17 μg of AUG(U)n	0·61	0·18
15 μg of GUG(U)n	0·67	0·10
4 μg of EMC RNA	0·12	1·19
(*B*) Endogenous RNA	0·28	1·58

(*A*) Incorporations were carried out in a total of 50 μl. containing 20 mM Tris HCl *p*H 7·5, 120 mM KCl, 5 mM Mg^{2+}, 6 mM β-mercaptoethanol, 0·09 mg of creatine phosphate, 10 μg of creatine phosphokinase, 1 mM ATP, 0·1 mM GTP and 25 μM of each of the twenty amino-acids. All incubations contained 0·2 mg of S150 protein and 50 μg of ribosomes. 3·5 jsMoles of either of the separated ascites cell ^{35}S-Met-tRNAs were added and incubation continued for 30 min at 37° C. Reactions were stopped by addition of 5 per cent TCA containing 4 per cent casamino-acids and subsequently heated for 15 min at 90° C. The samples were collected on glass fibre paper, washed, and counted in a scintillation counter at 60 per cent efficiency. 1 *p*Mole equals 26,400 c.p.m. (*B*) Incorporations using a non-preincubated ascites cell S30 preparation which contained the same ingredients as for (*A*) except that 0·25 mg of non-preincubated S30 was added instead of S150 and ribosomes.

Table 2. END GROUP DETERMINATION OF ^{35}S METHIONINE LABELLED POLYPEPTIDE PRODUCT SYNTHESIZED IN RESPONSE TO RANDOM POLY AUG AND POLY UG

Polymer	Per cent N-terminal incorporation from (1) ^{35}S-Met-tRNA$_F$*	(2) ^{35}S-Met-tRNA$_M$*
poly-AUG	89	3
poly-UG	95	5

Incorporations were carried out in a total of 100 μl., in the conditions described in Table 1. After 30 min at 37° C, 100 μl. of 100 mM EDTA containing 10 μg of pancreatic ribonuclease was added and incubation continued for 2 min. The samples were precipitated with 5 per cent TCA containing 4 per cent casamino-acids, washed several times with 5 per cent TCA, and finally dried. End group determinations were then carried out using a modified Edman procedure[14]. After exposure to trifluoroacetic acid the thiazolinones were extracted with 1,2-dichloroethane. The resulting organic phase was evaporated to dryness, taken up in formic acid and aliquots taken for counting. The residual protein was partially hydrolysed in 6 N HCl, dried and finally dissolved in formic acid; aliquots were then taken for counting.

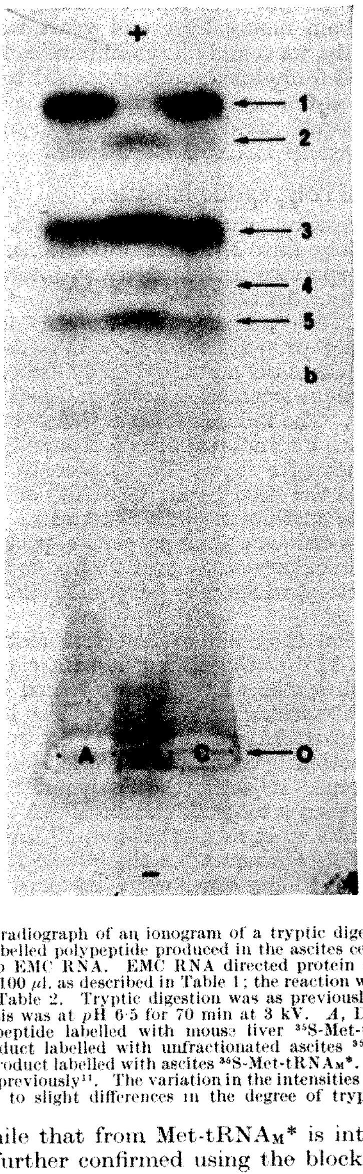

Fig. 3. Autoradiograph of an ionogram of a tryptic digest of the ^{35}S-methionine labelled polypeptide produced in the ascites cell-free system in response to EMC RNA. EMC RNA directed protein synthesis was performed in 100 μl. as described in Table 1; the reaction was stopped as described in Table 2. Tryptic digestion was as previously described[11]. Electrophoresis was at *p*H 6·5 for 70 min at 3 kV. *A*, Digest of virus specific polypeptide labelled with mouse liver ^{35}S-Met-tRNA$_M$*; *B*, digest of product labelled with unfractionated ascites ^{35}S-Met-tRNA; *C*, digest of product labelled with ascites ^{35}S-Met-tRNA$_M$*. Peptides are numbered as previously[11]. The variation in the intensities of some of the bands is due to slight differences in the degree of tryptic digestion.

We have demonstrated that virus specific polypeptide(s) are synthesized in the ascites cell-free system primed by EMC RNA[11]. Subsequent investigation of the virus specific polypeptide product synthesized in these conditions has revealed that alanine is the N-terminal amino-acid. Thus all methionine residues in this product must be internal. Table 1 indicates that only Met-tRNA$_M$* incorporates methionine into virus specific polypeptide in response to EMC RNA. Very little, if any, incorporation is detected using Met-tRNA$_F$*. This conclusion was further confirmed by comparing a tryptic digest of the virus specific product labelled by unfractionated Met-tRNA with a similar digest of the product labelled by Met-tRNA$_M$* only. Fig. 3 shows that Met-tRNA$_M$* donates all the methionine residues normally found in the product made using unfractionated tRNA. If methionine from Met-tRNA$_F$* is incorporated into the N-terminal position of the virus specific protein, then it must be rapidly removed again, presumably by an aminopeptidase.

Endogenous protein synthesis in non-preincubated S30 preparations from ascites tumour cells with the separated Met-tRNAs gave essentially similar results (Table 1).

All these experiments were repeated using the separated Met-tRNAs from mouse liver and yeast with identical results. Finally, we would like to emphasize that we have never detected formylmethionine attached to tRNA$^{Met}_{F*}$ in the ascites cell-free system, nor has it been found in polypeptides synthesized in response to synthetic polymers[15], endogenous RNA or EMC RNA.

Mechanism of Polypeptide Initiation

Our experiments show that Met-tRNA$_F$* donates methionine only into N-terminal positions, while Met-tRNA$_M$* incorporates methionine into internal positions of polypeptides. In addition, Met-tRNA$_M$* responds to the codon AUG[8,9,16], whereas Met-tRNA$_F$* has the same unusual coding properties as *E. coli* fMet-tRNA$_F$, responding both to AUG and GUG on 80S ribosomes. This indicates a unique interaction between this tRNA and the 80S ribosome. The failure of Met-tRNA$_F$* to incorporate methionine into internal positions presumably means that mammalian transfer factor T-I is able to discriminate against it. On the other hand, the ability of Met-tRNA$_F$* to incorporate methionine into N-terminal positions, in addition to its unique coding properties, probably reflects the presence in eukaryotic cells of a separate set of factors (initiation factors) which may be specific for Met-tRNA$_F$* only.

In conclusion the unique structural features of prokaryotic tRNA$^{Met}_F$ distinguishing it as a chain initiating tRNA in such systems have been retained in the corresponding species in higher organisms. The interaction of eukaryotic Met-tRNA$_F$* and the 80S ribosome is identical to the interaction between prokaryotic Met-tRNA$_F$ and the 70S ribosome. Rejecting the highly unlikely possibility that tRNA$^{Met}_{F*}$ is a totally redundant tRNA in eukaryotic cells, our results must mean that Met-tRNA$_F$* is a chain initiator on 80S ribosomes for the simple reason that it cannot function in any other way. At the same time the notion that any amino-acyl-tRNA can initiate on 80S ribosomes can also be rejected because Met-tRNA$_M$* clearly cannot do so. The possibility that Met-tRNA$_F$* is merely a source for mitochondrial fMet-tRNA$_F$ also seems unlikely because all the experiments described here have been performed on cytoplasmic ribosomes. In addition, the amount of cytoplasmic tRNA$^{Met}_{F*}$ (that is, 1–2 per cent of total tRNA) is vastly greater than that found in the mitochondria.

Thus there seem to be three likely models for initiation on 80S ribosomes. First, Met-tRNA$_F$* without the formyl group is the only chain initiator on 80S ribosomes, and incorporates methionine into the N-terminal position of all nascent proteins. If this is so, the methionine must be removed again in most cases, since it is not a common N-terminal amino-acid in eukaryotes. Further, we have not so far detected any N-terminal methionine in the product synthesized in response to EMC RNA, nor has it been reported in rabbit reticulocyte haemoglobin synthesis. Such a theory would make initiation on 80S ribosomes virtually identical to that on 70S ribosomes, the only difference being the lack of formylation and a slight modification in the specificity of cytoplasmic initiation factors.

Second, Met-tRNA$_F$* could select the reading frame only and not be incorporated into proteins. Met-tRNA$_F$* can incorporate methionine in response to synthetic polymers but the situation might be different with natural messenger RNAs. Earlier experiments with rabbit reticulocyte cell-free systems have shown that modified valyl-tRNA is incorporated into the N-terminal position of nascent haemoglobin[17]. These two models for initiation can explain these results by arguing that in such systems the messenger RNA is always attached to the ribosomes and thus the first step in initiation involving Met-tRNA$_F$* may already be completed.

Third, a class of cytoplasmic tRNAs might exist with structural features identical to tRNA$^{Met}_{F*}$. Such tRNAs would thus be specifically adapted for their role as chain initiators.

We thank Mr M. J. Young for technical assistance, and Dr J. Brown for blocked oligonucleotide polymers. A. E. S. is an MRC scholar.

After completion of our manuscript we noted a recent paper by Takeishi, Sekiya and Ukita (*Biochim. Biophys. Acta*, **199**, 559; 1970), who have shown that only yeast and *E. coli* Met-tRNA$_M$ donate methionine into haemoglobin synthesized in a rabbit reticulocyte cell-free system.

Initiator Codons in Eukaryotes

by

J. C. BROWN
A. E. SMITH

MRC Laboratory of Molecular Biology,
Hills Road, Cambridge CB2 2QH

A unique interaction between eukaryotic Met-tRNA$_{F*}$, AUG and 80S ribosomes is demonstrated. It is suggested that tRNA$^{Met}_{F*}$ is the only initiator tRNA on 80S ribosomes and that AUG and possibly GUG are the initiator codons.

THE cytoplasm of several eukaryotes contains two methionine accepting tRNAs (tRNA$^{Met}_{F*}$ and tRNA$^{Met}_{M*}$)[2]. Methionine attached to tRNA$^{Met}_{F*}$ can be formylated by *Escherichia coli* transformylase[1], while Met-tRNA$_{M*}$ does not accept formyl groups. In an *E. coli* cell-free system eukaryotic fMet-tRNA$_{F*}$ functions as an initiator with the same requirements and specificity as *E. coli* fMet-tRNA$_F$ (refs. 2 and 3). The preceding article demonstrates that in a mammalian cell-free system Met-tRNA$_{F*}$ donates methionine exclusively into N-terminal position$_*$ of newly synthesized polypeptides, while Met-tRNA$_{MS}$ donates methionine only into internal positions[2]. Thus discrimination against the Met-tRNA$_{F*}$ type of species by the corresponding aminoacyl-tRNA binding enzymes

(T on 70S and T–I on 80S) seems to be identical for the two ribosomal systems[2,4]. This suggests that Met-tRNA$_{\mathrm{F}*}$ is a chain initiator on 80S ribosomes, although not necessarily the only one. Here we show that the interaction between Met-tRNA$_{\mathrm{F}*}$, AUG and the 80S ribosome is unique, closely resembling the corresponding interaction between prokaryotic fMet-tRNA$_{\mathrm{F}}$, AUG and the 70S ribosome. (The term 80S ribosome is adopted for convenience: it is quite probable that the interaction described here first occurs on the 40S ribosomal subunit.) No other aminoacyl-tRNA tested shows a similar interaction with its corresponding codon on the 80S ribosome. These results therefore imply that Met-tRNA$_{\mathrm{F}*}$ is the only chain initiator tRNA on 80S ribosomes and that AUG and possibly GUG are the only initiator codons in eukaryotes.

Propagation of Krebs II mouse ascites tumour cells, preparation of the cell-free system, and fractionation of the tRNA were performed as previously described[2]. Synthetic polynucleotide mRNAs were prepared by established procedures using the enzyme polynucleotide phosphorylase[5]. The base sequence of the products was verified by ribonuclease digestion followed by identification of the digestion products by chromatography.

AUG as Initiator Codon

In a cell-free system derived from ascites tumour cells, Met-tRNA$_{\mathrm{F}*}$ donates the methionine incorporated into the polypeptide product synthesized in response to AUG(U)$_{\bar{n}}$($\bar{n}$ = 35)[2]. No incorporation of methionine from Met-tRNA$_{\mathrm{M}*}$ is detected. Similarly, only Met-tRNA$_{\mathrm{F}*}$ donates methionine in response to GUG(U)$_{\bar{n}}$[2]. Further experiments have now shown that there is virtually no incorporation of valine in these conditions, although there is a very efficient incorporation of valine in response to random poly(U,G). Thus, when presented with an AUG or GUG at the 5′ end of a synthetic messenger RNA, the 80S ribosome interacts only with Met-tRNA$_{\mathrm{F}*}$ and discriminates against Met-tRNA$_{\mathrm{M}*}$ and Val-tRNA.

Table 1 records the results obtained using a series of polymers in which the AUG was located at different distances from the 5′ end. In all cases methionine is donated by Met-tRNA$_{\mathrm{F}*}$. That very little incorporation from Met-tRNA$_{\mathrm{M}*}$ or Lys-tRNA could be detected further indicates that synthesis is initiated almost exclusively at the AUG position. Thus an AUG at or near the 5′ end of synthetic mRNA signifies Met-tRNA$_{\mathrm{F}*}$. Furthermore, the interaction between Met-tRNA$_{\mathrm{F}}$* and this particular AUG results in a phasing effect; the mRNA is read almost exclusively from AUG and not in other possible reading frames. The ability of the 80S ribosome to distinguish Met-tRNA$_{\mathrm{F}*}$ and not Met-tRNA$_{\mathrm{M}*}$ in response to an AUG in such a position most probably results from the presence of initiation factors which mediate this specific interaction. Similar arguments can be made for recognition of GUG as Met-tRNA$_{\mathrm{F}*}$ and not Val-tRNA.

In the presence of low Mg^{2+} concentrations only polymers containing AUG and GUG are translated in the *E. coli* cell-free system[6]. In such conditions, initiation on the 70S ribosome "by mistake" is apparently no longer possible. Synthesis in response to AUG and GUG polymers then strictly depends on the presence of initiation factors and fMet-tRNA$_{\mathrm{F}}$. Removal of the initiation factors completely abolishes synthesis[6]. Omission of the formyl group on Met-tRNA$_{\mathrm{F}}$ also abolishes synthesis[7], because the initiation factors are specific for fMet-tRNA (ref. 8). They do not recognize Met-tRNA$_{\mathrm{F}}$, and consequently no interaction can then occur between this tRNA and the 70S ribosome. In such conditions polymers containing AUG behave identically to all other polymers.

Table 1. INCORPORATION OF ^{35}S-METHIONINE FROM SEPARATED Met-tRNAs FROM ASCITES TUMOUR CELLS

Additions	pmoles ^{35}S-methionine incorporated from (1) ^{35}S-Met-tRNA$_{\mathrm{F}*}$	(2) ^{35}S-Met-tRNA$_{\mathrm{M}*}$
None	0·05	0·16
AUG(U)$_{\bar{n}}$	0·52	0·11
AAUG(U)$_{\bar{n}}$	0·42	0·12
AAAUG(U)$_{\bar{n}}$	0·27	0·11
AAAAUG(U)$_{\bar{n}}$	0·30	0·14
AAAAAUG(U)$_{\bar{n}}$	0·28	0·13
A$_{10}$UG(U)$_{\bar{n}}$	0·27	0·19

Incorporations were carried out in a total of 50 µl. in the conditions described previously[2]. The Mg^{2+} concentration was 5 mM. 15·5 µg of oligonucleotide polymer was added as indicated, and 3·5 pmoles of either of the separated ^{35}S-Met-tRNAs added to each incubation. 1 pmole corresponded to 26,400 c.p.m. Small but measurable amounts of lysine were incorporated from ^{14}C-lysyl-tRNA with A$_5$UG(U)$_{\bar{n}}$ and A$_{10}$UG(U)$_{\bar{n}}$. $\bar{n}$ is in all cases approximately 35.

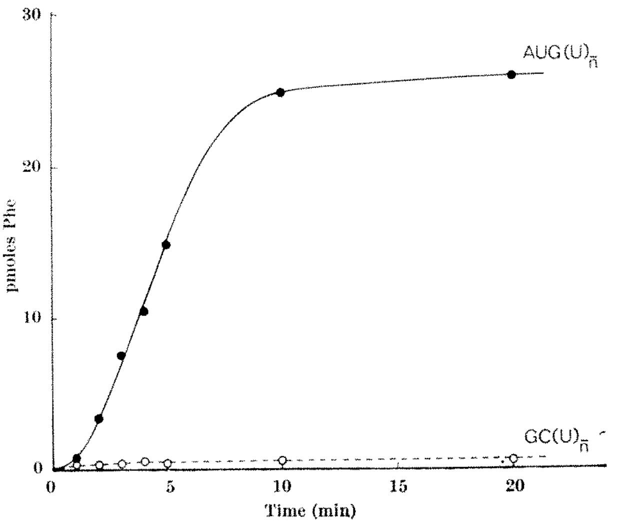

Fig. 1. Incorporation of phenylalanine in response to AUG(U)$_{\bar{n}}$ and GCU(U)$_{\bar{n}}$ in the ascites cell-free system at 2 mM Mg^{2+} concentration. Incorporations were carried out in a total of 250 µl. in conditions similar to those described previously[2]. The contents of each incubation included half the normal amount of ribosomes and S150, 0·6 µCi of ^{14}C-phenylalanine, 10 nmoles of each of the nineteen other amino-acids and 50 µg of synthetic polynucleotide. The Mg^{2+} concentration was 2·25 mM. 25 µl. aliquots were removed at the times indicated, and prepared for counting as previously described. 1 pmole corresponds to 660 c.p.m. The product synthesized in the presence of ^{35}S-methionine or ^{3}H-phenylalanine in response to AUG(U)$_{\bar{n}}$ was identified by digestion of the polypeptide with chymotrypsin, followed by electrophoresis of the digestion product at pH 3·5. The only ^{35}S-methionine labelled peptide co-electrophoresed with marker Met-Phe; the ^{3}H-phenylalanine-labelled peptides co-electrophoresed with Phe-Phe and Met-Phe ($\bar{n}$ is in both cases ≃35).

In the ascites cell-free system, conditions can be found where only synthetic polymers containing AUG are translated. Fig. 1 shows that at approximately 2 mM Mg^{2+} concentration AUG(U)$_{\bar{n}}$ is translated while GCU(U)$_{\bar{n}}$ is not. The incorporation in response to AUG(U)$_{\bar{n}}$ is at least 50 per cent of that obtained at the optimal Mg^{2+} concentration. In addition, AUG(U)$_{\bar{n}}$ has a lower Mg^{2+} optimum than that observed for all other polynucleotide mRNAs tested. Experiments using the polymers shown in Table 2 indicate that they all behave identically to GCU(U)$_{\bar{n}}$, and give no phenylalanine incorporation at 2 mM Mg^{2+} concentration. All polymers are active at 5 mM Mg^{2+} concentration, with activities being comparable with that of AUG(U)$_{\bar{n}}$. In these conditions, however, only AUG(U)$_{\bar{n}}$ and GUG(U)$_{\bar{n}}$ are initiated with high

Table 2. PHENYLALANINE INCORPORATION WITH DIFFERENT POLYNUCLEOTIDES

UUU(U)$_{\overline{35}}$

AAG(U)$_{\overline{35}}$
GAU(U)$_{\overline{35}}$
GAA(U)$_{\overline{35}}$
UGU(U)$_{\overline{35}}$
CGU(U)$_{\overline{35}}$
AGU(U)$_{\overline{35}}$

The above synthetic polynucleotides were tested in the ascites cell-free system in the conditions described in Fig. 1, and gave no incorporation of phenylalanine at 2 mM Mg^{2+}.

Table 3. INCORPORATION OF ^{35}S-METHIONINE FROM ASCITES fMet-tRNA$_{F*}$ AND Met-tRNA$_{F*}$ IN RESPONSE TO RANDOM POLY AUG IN THE *E. coli* AND ASCITES CELL-FREE SYSTEMS

Cell-free system	pmoles of ^{35}S methionine incorporated from (1) ^{35}S fMet-tRNA$_{F*}$	(2) ^{35}S Met-tRNA$_{F*}$
E. coli	0·53	0·71
Ascites	0·09	0·66

Incorporations were carried out in a total of 50 µl. in standard conditions. The Mg^{2+} concentration in the *E. coli* S30 was 11 mM and in the ascites system was 5 mM. 50 µg of random poly AUG was added to each incubation. Purified ascites tRNA$^{Met}_{F*}$ was charged in the presence of *E. coli* transformylase and formyl donor and subsequently pyrophosphorylysed to remove unformylated Met-tRNA. The degree of formylation was checked by pancreatic digestion followed by electrophoresis at *p*H 3·5. 2·6 pmoles of fMet-tRNA$_{F*}$ or 3·3 pmoles of Met-tRNA$_{F*}$ were added as indicated. 13,000 c.p.m. correspond to 1 pmole.

efficiency from the 5′ end. The remaining polymers incorporate only small amounts of the amino-acid corresponding to the codon at the 5′ end. This is comparable with the result obtained in the *E. coli* cell-free system using similar polymers[9]. Experiments with polymers which have a radioactive triplet at the 5′ end showed that they were not rapidly broken down in the cell-free system. Further, no difference in half life between ^{14}C-labelled AUG(U)$_{\bar{n}}$ and that of other polymers could be detected. Thus our results cannot be explained by preferential stability of AUG(U)$_{\bar{n}}$ towards ribonuclease digestion.

Formation of the Initiation Complex

At low Mg^{2+} concentrations, therefore, only polymers containing AUG are translated in this mammalian cell-free system. By analogy with the similar situation in *E. coli*, we submit that this must mean that initiation factors are present in our cell-free system and that these factors are specific for Met-tRNA$_{F*}$. fMet-tRNA$_{F*}$ formylated by *E. coli* transformylase is not active in the cell-free system as shown in Table 3, indicating that the 80S ribosome does not interact with blocked aminoacyl-tRNAs. It should be noted also that fMet-tRNA or any similar derivatives have never been detected in the cytoplasm of eukaryotic organisms[3].

Our results indicate that a special interaction occurs between Met-tRNA$_{F*}$, AUG and the 80S ribosome. This interaction is identical in all respects to that occurring in the formation of the initiation complex on the 70S ribosome with fMet-tRNA$_F$ and AUG (ref. 10). Thus an AUG codon at or near the 5′ end of an mRNA signifies Met-tRNA$_{F*}$ and not Met-tRNA$_{M*}$. Similarly, GUG at the 5′ end of the mRNA indicates Met-tRNA$_{F*}$ and not Val-tRNA. The 80S ribosome is therefore able to discriminate between these possibilities without confusion. In addition, the presence of an AUG sequence at or near the 5′ end of an mRNA selects the reading frame, translation of other possible codons being severely suppressed. At low Mg^{2+} concentrations only polymers containing an AUG codon are translated.

If 80S ribosomal systems contain initiation factors which are specific for Met-tRNA$_{F*}$, Met-tRNA$_{F*}$—without a formyl group—must be the only chain initiator in such systems, with AUG and possibly GUG as the initiator codons. A consequence of this model for eukaryotic initiation is that all nascent proteins contain a methionine residue in front of the normal N-terminal amino-acid. The methionine residue must, in most cases, be subsequently removed by an aminopeptidase, for methionine is not a common N-terminal amino-acid in eukaryotes. There is already some evidence for this hypothesis. In a recent study of initiator mutants in yeast[11], several isocytochrome *c* mutants were isolated which had methionine as an additional amino-acid at the N-terminal position. It was concluded that the isocytochrome *c* mRNA contains an AUG codon which precedes the codon for the normal N-terminal amino-acid of the mature protein. Furthermore, methionine is incorporated into the N-terminal position of cytochrome *c*, to be removed again later, thus exposing the normal N-terminal amino-acid, threonine. These studies are in agreement with the results presented here and in the previous article. The similarity of eukaryotic polypeptide chain initiation with the corresponding process on 70S ribosomes is thus almost complete, the only difference between the two systems being the lack of formylation of Met-tRNA$_{F*}$ and a slight alteration in the specificity of the initiation factors in the 80S ribosomal system.

We thank Professor K. A. Marcker for his advice, encouragement and help with the manuscript. One of us (J. C. B.) is a NATO postdoctoral fellow. A. E. S. is an MRC scholar.

Animal RNA synthesized in the presence of actinomycin D is 40 per cent resistant to ribonucleases A and T_1, unmethylated and polydisperse on sucrose density gradients. The ribonuclease resistant core possesses properties of double-stranded RNA although the base composition suggests that it is not a simple base-paired structure.

ACTINOMYCIN D selectively inhibits DNA dependent RNA synthesis by complexing with the DNA template. At high concentrations (1·0–5·0 µg/ml.) it has been shown to inhibit more than 95 per cent of RNA synthesis in animal cells[1,2]. RNA synthesized in the presence of actinomycin has been observed previously[3–7], but it has never been adequately characterized. We have studied the residual RNA synthesis occurring in the presence of actinomycin in a number of animal cell lines and in mammalian tissue. Our observations suggest that this material, though it

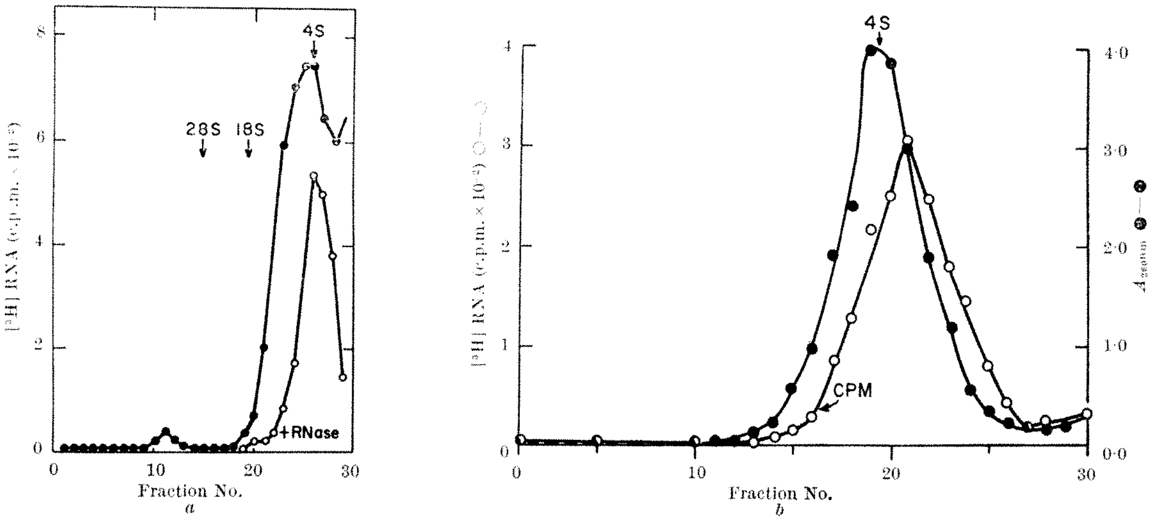

Fig. 1. Sucrose density gradient centrifugation of RNA synthesized in the presence of actinomycin in Burkitt lymphoma cells. RNA was dissolved in 2 × SSC (*a*) and divided into two aliquots. One was incubated with ribonuclease A (24 μg/ml. for 30 min at 37° C) followed by incubation with pronase (1·5 mg/ml. for 1 h at 37° C). The second aliquot was not treated. The two preparations were layered on separate tubes containing a 6 to 30 per cent gradient of sucrose, together with 0·1 ml. of rat liver cytoplasmic RNA containing four absorbance units at 260 nm, and sedimented for 50 min at 300,000*g*. Fractions were collected and analysed for absorbance at 260 nm and trichloroacetic acid precipitable ³H-RNA was determined as described in the text. The results from the two preparations are illustrated in the single figure. Arrows indicate the peak of absorbance of the rat liver RNAs. In *b* RNA treated with ribonuclease A and pronase was layered on a tube containing a 6 to 30 per cent gradient of sucrose together with marker *E. coli* B tRNA and sedimented at 300,000*g* for 5 h. Profiles of both absorbance of the tRNA marker and the trichloroacetic acid precipitable ³H-RNA are given.

has many of the attributes of a double-stranded RNA, is not a simple base-pair structure. RNA synthesis in the presence of actinomycin D was examined in animal cells from a wide variety of sources. ³H-uridine was incorporated into RNA in actinomycin treated cells at a rate which was 0·8–2·3 per cent of that found in untreated cells. Such incorporation was seen in all animal cells examined (Table 1). The size distribution of the RNA molecules synthesized by Burkitt lymphoma cells in the presence of actinomycin was examined by zone centrifugation on a sucrose density gradient (Fig. 1*a*). Labelled RNA was distributed between 4S and 14S with a peak at approximately 7S. Similar profiles were obtained for RNA from all the cell lines listed in Table 1.

RNA viruses replicate normally in actinomycin treated cells. This suggested that the RNA synthesized in the presence of actinomycin in our cells might have properties similar to those reported for viral RNA. The replicative cycle of RNA viruses is associated with ribonuclease-resistant structures[19]. We examined the susceptibility of the RNA synthesized in the presence of actinomycin to digestion by ribonucleases. As shown in Table 1, 40–68 per cent of the RNA remained acid insoluble after treatment with ribonuclease A. Incubation of this ribonuclease resistant core RNA with T_1 ribonuclease, deoxyribonuclease or pronase had no further effect on the level of acid precipitable RNA (Tables 2 and 3).

The ribonuclease resistant core of the RNA synthesized in the presence of actinomycin co-sedimented with a 4S RNA marker in a sucrose gradient run at 300,000*g* for 50 min. When sedimentation time was increased to 300 min, the core RNA continued to run as a homogeneous peak but with an *s* value of 3·4S relative to marker tRNA (Fig. 1*b*).

Further study of the RNA synthesized in the presence of actinomycin was carried out by molecular sieve chromatography on a column of 'Sephadex *G*-100'. This technique resolves 5S RNA from 4S RNA which sediment together on sucrose density gradients. Burkitt lymphoma cell RNA synthesized in the presence of actinomycin and chromatographed on a 'Sephadex *G*-100' column was resolved into three components (Fig. 2*a*). The higher molecular weight RNA emerged in the void volume trailing behind the first peak of marker ribosomal RNA from rat liver cytoplasm. This portion of the RNA was partially excluded and partially retarded by 'Sephadex *G*-100'. The middle and largest peak co-eluted with the peak of marker 5S RNA (fraction 49, Fig. 2*a*). The last and smallest peak corresponded to the 4S region of the chromatogram. The core RNA eluted with marker 4S RNA from the 'Sephadex *G*-100' column (Fig. 2*b*). Similar profiles were obtained from other cell lines and from the RNA extracted from the liver cytoplasm of actinomycin treated rats. RNA synthesis in the presence of actinomycin has been demonstrated previously in rat liver[3,4]. This RNA contains pseudouridine and is assumed to be tRNA though no amino-acid acceptance has been demonstrated. Because a portion of the RNA synthesized in the presence of actinomycin from cell lines and from rat liver co-eluted with marker tRNA in the present experiment, we examined the methylated base content of the RNA from Burkitt cells to determine if the RNA synthesized in the presence of actinomycin were in part tRNA. Actinomycin treated Burkitt cells were labelled with [^{3}H-methyl] methionine for 40 min and the RNA which had been extracted at 23° C without sodium dodecyl sulphate (SDS) was chromatographed on a 'Sephadex *G*-100' column. Labelled ribosomal RNA is not extracted in these conditions[11]. All labelled material emerged with the marker 4S RNA peak (7,800 c.p.m.), but no acid precipitable labelled material remained after digestion with ribonuclease A. This suggested that the RNA synthesized in the presence of actinomycin contained no methylated bases and was not tRNA. Presumably the observed methyl labelling occurred in relation to the previously synthesized tRNAs. The latter, however, was completely sensitive to ribonuclease digestion, unlike the RNA synthesized in the presence of actinomycin.

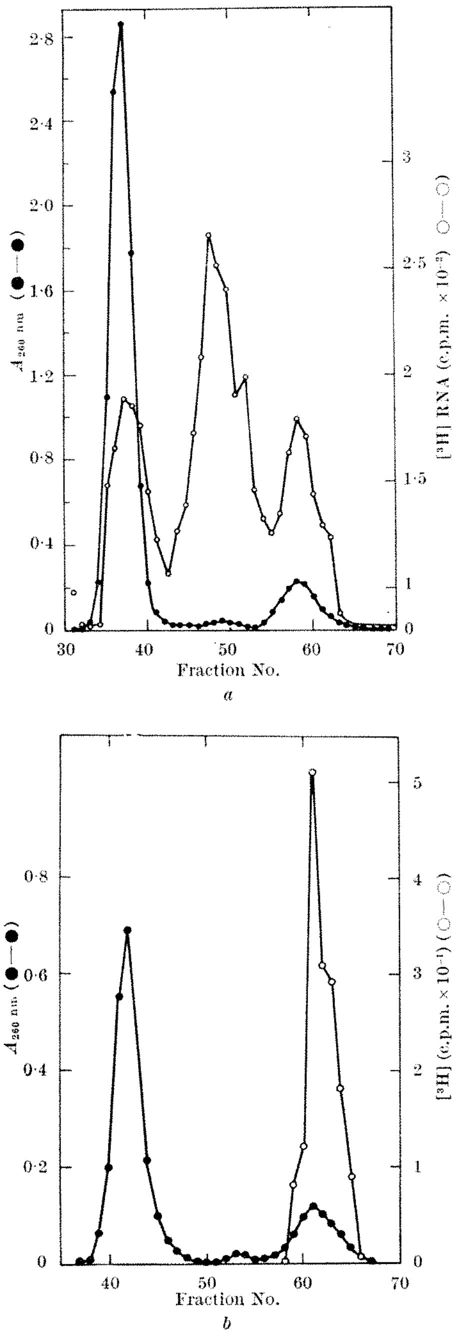

Fig. 2. 'Sephadex *G*-100' chromatography of RNA synthesized in the presence of actinomycin in Burkitt lymphoma cells. RNA was dissolved in 2 × SSC and (*a*) placed on a column together with 0·5 ml. rat liver cytoplasmic RNA containing fifteen absorbance units at 260 nm. In *b* RNA was first digested with ribonuclease A (24 μg/ml. for 30 min at 37° C) followed by incubation with pronase (1·5 mg/ml. for 1 h at 37° C) and placed on a column together with marker rat liver RNA. The column buffer contained 0·2 M NaCl, 0·02 M Tris-HCl (*p*H 7·4), and 2 mM EDTA. 3 ml. fractions were collected. Trichloroacetic acid precipitable ^{3}H-RNA was determined as described in the text.

Further evidence that this RNA was not tRNA was obtained from a study of the rate and extent of hydrolysis by ribonuclease (2·5 μg/ml. at 0° C in 0·2 M NaCl, 0·02 M Tris-HCl buffer, *p*H 7·4, 5 mM $MgCl_2$ at 0° C) of 4S and 5S ^{3}H-labelled RNA from rat liver cytoplasm. After 2 min incubation, 90 per cent of 5S RNA and 38 per cent of the 4S RNA had been hydrolysed. ^{3}H-RNA from Burkitt lymphoma cells synthesized in the presence of actinomycin was degraded by 12 per cent in these conditions. The RNA synthesized in the presence of actinomycin was therefore different from both 5S and most of the 4S RNA of mammalian cells. The distribution of ^{3}H among the nucleotides of the RNA synthesized in the presence of actinomycin following ^{3}H-uridine labelling was examined. After alkaline hydrolysis less than 3 per cent of the label was found in cytidine nucleotides. This ruled out the possibility that the labelling of the 4S component of the RNA synthesized in the presence of actinomycin arises from addition to the 3′ terminus of tRNA.

A series of experiments was performed to demonstrate that RNA was the material containing the radioactive label. The ribonuclease-resistant core of the RNA synthesized in the presence of actinomycin was completely hydrolysed by KOH and was stable to deoxyribonuclease and pronase treatments (Table 3). No label was incorporated into the RNA extracted from actinomycin treated Burkitt cells when ^{3}H-thymidine (20 μCi/ml. for 30 min) was used, thus ruling out a DNA–RNA hybrid RNA. In addition, the RNA synthesized in the presence of actinomycin was found in the aqueous layer following phenol extraction. A DNA–RNA hybrid would have been associated with the interphase or middle layer[10]. RNA was not an artefact of actinomycin treatment because ribonuclease resistant RNA was also obtained from Burkitt cells labelled in the absence of actinomycin. The chromatographic profile of the latter RNA on benzoylated DEAE-cellulose was identical to that of the ribonuclease resistant RNA synthesized in the presence of actinomycin.

Work on RNA bacteriophages has shown that single stranded RNA may be converted to a double stranded form during extraction[20]. The effect of extraction of RNA from Burkitt cells was examined in two ways. To test the effect of phenol deproteinization, actinomycin treated Burkitt cells were lysed with SDS after labelling with ^{3}H-uridine and then deproteinized by passing the material through a silicic acid column[21]. The RNA was then treated with ribonuclease and passed through a benzoylated DEAE-cellulose column. The level of ribonuclease resistance and the chromatographic properties on benzoylated DEAE-cellulose of this material were similar to those of phenol extracted RNA. The effects of detergent and omission of deproteinization were then examined. The supernatant from Burkitt cells, disrupted with a Dounce homogenizer in the absence of detergent, was placed on a sucrose gradient with and without ribonuclease pretreatment. A profile similar to that in Fig. 1*a* was obtained except that the labelled RNA now sedimented more rapidly. The peak of labelled RNA sedimented at 10S and 26S respectively, in the presence and absence of ribonuclease, when deproteinization was omitted. This suggested that either the RNA synthesized in the presence of actinomycin is of larger *s* value in the intact cell and is partially degraded by extraction, or that proteins are closely associated with this RNA in the cell.

The ribonuclease resistant core of the RNA synthesized in the presence of actinomycin had several properties of a double-stranded RNA. When this RNA was dissolved in $0{\cdot}1\times$SSC instead of $2\times$SSC (SSC = 0·15 M NaCl–0·015 M sodium citrate, *p*H 7·0) there was a loss of all detectable labelled acid insoluble material on further ribonuclease treatment (Table 2). Such stability to ribonuclease at high ionic strength and susceptibility at low ionic strength has been used as a criterion for a double-stranded RNA[20–25]. On columns of benzoylated DEAE-cellulose[14,26] which resolves mammalian RNAs on the basis of secondary structure during elution on a gradient of NaCl[15], the ribonuclease resistant core eluted with a synthetic homopolymer duplex poly I·poly C. This RNA also elutes with the entirely base paired replicative form of the RNA virus, Semliki Forest virus (unpublished data). This suggested that the ribonuclease resistant core of the RNA synthesized in the presence of actinomycin is an entirely base paired duplex.

The melting profile of the ribonuclease resistant core RNA was determined by assaying ribonuclease sensitivity of preparations heated to different temperatures. A transition was observed at 70° C, which was compatible with a highly structured RNA[27].

Table 4. BASE COMPOSITION OF CHICK EMBRYO FIBROBLAST ^{32}P-RNA SYNTHESIZED IN THE PRESENCE OF ACTINOMYCIN D AND RESISTANT TO HYDROLYSIS BY PANCREATIC RIBONUCLEASE

Base	Moles per cent
Uridylic acid	23·3
Guanylic acid	30·8
Cytidylic acid	23·9
Adenylic acid	22·0

In spite of these findings the base composition of the RNA is incompatible with an entirely base paired structure. Base composition studies revealed that the ribonuclease resistant core RNA from chick embryo fibroblasts had a high guanine content (Table 4). Additional observations suggested that this RNA had unusual features and was not a simple base paired structure. Heating to 100° C and rapid cooling disrupt double stranded RNAs, making them entirely sensitive to pancreatic ribonuclease. Treatment with dimethyl sulphoxide (DMSO) followed by dialysis[28] has the same effect. But after these treatments, only 60 per cent of the ribonuclease resistant core became sensitive to ribonuclease; 40 per cent of the material remained acid precipitable. This residual acid precipitable RNA can also be observed at temperatures above the T_m.

Ribonuclease A treatment may be expected to generate nuclease resistant oligomers with the general formula (purine)$_n$ pyrimidine. Such fragments would have been susceptible to further digestion with T_1 ribonuclease, but no change in acid precipitable material was observed following this treatment (Table 3, expt. 3). This indicates that the core RNA was not a large (purine)$_n$ pyrimidine oligonucleotide. Another structure which can be invoked from the base composition is a base paired molecule associated with a pG rich polymer. Heating to 100° C, rapid cooling, followed by ribonuclease digestion would have left such a proposed pG rich strand largely intact and would have accounted for the residual acid precipitable RNA observed. This possibility is ruled out because the RNA is not susceptible to T_1 ribonuclease digestion. Table 3, experiment 5, demonstrated that the 40 per cent residual RNA remains intact after T_1 treatment. It is possible that a collection of pG rich fragments could aggregate and behave like large oligonucleotides with a sufficiently high degree of secondary structure to resist melting and T_1 digestion[29]. But when the RNA synthesized in the presence of actinomycin was treated with T_1 ribonuclease either before or simultaneously with exposure to pancreatic ribonuclease, no difference was observed in the resulting level of ribonuclease resistant material.

Unusual Form of RNA

The evidence suggests a species of RNA in animal cells which is synthesized in the presence of actinomycin D. It is 40 per cent resistant to hydrolysis by ribonucleases A and T_1, a smaller portion also resistant to hydrolysis following heat and DMSO denaturation. No single explanation exists for all these findings. Among the many possibilities is that the RNA is transcribed from a protected or actinomycin resistant region of the DNA genome, or transcribed within a cell structure impermeable to actinomycin[30]. Alternatively, the RNA may be synthesized on an RNA template. A latent RNA virus in cell lines could be invoked, but this would suggest that latent RNA viruses are ubiquitous in animal cells. The RNA may represent replication of an RNA plasmid, but such a mode of synthesis has never been observed in animal cells.

Many actinomycin resistant reactions in mammalian cells result in ribonucleosides being converted to acid-insoluble forms, including polyadenylate synthesis[31] and chain extension of pre-existing polynucleotides[32–38]. These reactions have not been ruled out entirely as the basis for the present observations, but the products differ from the RNA being discussed in base composition and resistance to ribonuclease.

The ribonuclease-resistant core of the RNA synthesized in the presence of actinomycin could be attributed to either a high degree of secondary structure or to covalently bound groups and base substitutions. Bound amino-acids or peptides, and intermolecular disulphide bridges[37], could explain the small portion of RNA resistant to ribonuclease digestion following heat and DMSO denaturation. The increased *s* value of this RNA when deproteinization was omitted from the extraction procedure is support for this hypothesis. The RNA associated with nucleohistones[38] has many features in common with the present RNA, including partial resistance to ribonuclease.

Colby and Duesberg[23] have reported that vaccinia virus infection induces synthesis in chick embryo cells of a double-stranded RNA. This material has a thermal denaturation curve and equilibrium sedimentation characteristics of a double-stranded molecule. It also exhibits the difference in ribonuclease sensitivity in high and low salt typical of double-stranded molecules. No base composition data are reported. A smaller amount of partially ribonuclease-resistant RNA which did not hybridize with the vaccinia genome is present in uninfected chick cells. This material may be similar to the RNA reported here.

An understanding of the RNA synthesized in the presence of actinomycin has practical application in the examination of the product of RNA virus synthesis in animal cells. Replication of RNA viruses is studied routinely by inhibiting host RNA synthesis with high concentrations (1–5 μg/ml.) of actinomycin. The assumption is made that all subsequent RNA synthesis is viral specific. But, as shown by our experiments, a low level of host RNA synthesis persists. It cannot be assumed that all RNA fractions obtained from the infected host are, in fact, specified by the virus.

In conclusion, the assumption that the synthesis of all informational RNA in normal mammalian cells is directed by DNA templates must be held in abeyance until the origin of the present RNA has been determined.

Cultures, Extractions and Determinations

The methods used in preparing monolayers of primary chick fibroblasts and pools of the Semliki Forest virus for the preparation of the replicative form of the virus have been previously described[8]. Collection, purification and culture conditions for resting and phytohaemagglutinin stimulated human peripheral lymphocytes were described by Cooper[9]. Culture conditions for the Burkitt lymphoma cells were the same as those for normal lymphocytes except for the use of medium RPMI 1640 instead of Eagle's minimal essential medium. Lymphoid cells were preincubated with actinomycin (Merck, Sharp, and Dohme) at 5 μg/ml. for 30 min; other cell lines, at 2·5 μg/ml. All cells in suspension cultures were concentrated five-fold before the addition of ^{3}H-uridine, 20 μCi/ml. or [^{3}H-methyl]methionine, 20 μCi/ml. (New England Nuclear). For the latter, in RNA methylation experiments, cells were incubated in medium containing 0·05 the usual concentration of amino-acids plus 1 mM sodium formate. ^{32}P labelling experiments were performed with chick embryo fibroblasts. The monolayers were preincubated in low phosphate containing medium with 2 per cent serum for 30 min. Actinomycin was added for 30 min followed by carrier free ^{32}P-phosphoric acid (New England Nuclear), 0·2 mCi/plate, for an additional 40 min.

RNA was extracted[10,11] at 37° C in the presence of bentonite and SDS. Unlabelled cytoplasmic RNA from rat liver[12] was added to the final aqueous phase of the extraction procedure. RNA was washed twice and dissolved in 2 × SSC. When ribonuclease digestion was performed, samples were also treated with pronase (Calbiochem) (1·5 mg/ml. for 1 h at 37° C) to inactivate the ribonuclease[13].

Chromatography on the benzoylated DEAE–cellulose[14] (Schwarz BioResearch) column has been described[15]. 'Sephadex *G*-100' column (1·5 cm × 90 cm) chromatography was performed using a buffer containing 0·2 M NaCl, 0·02 M Tris-HCl (*p*H 7·4), 2 mM EDTA. Sucrose density gradients were analysed and the relative *s* values were calculated by previously described methods[16,17].

For the base composition determination of ^{32}P-RNA from chick embryo fibroblasts, the RNA resistant to ribonuclease A and T_1 (Worthington Biochemical) was passed through a benzoylated DEAE-cellulose column. The single peak of ^{32}P-RNA co-eluting with the synthetic homopolymer duplex poly I·poly C (Miles Laboratories) was hydrolysed for base analysis[18].

Tissues from rats following intraperitoneal injections of actinomycin and ^{3}H-orotic acid (Schwarz BioResearch) were obtained using the protocol of Revel and Hiatt[3].

We thank Mrs Marlene Gaunaurd and Mrs Irene Hughes for technical assistance, Dr Herbert L. Cooper for discussions, and Dr Alan S. Rabson for a gift of Burkitt lymphoma cells.

Origin of the Alpha Rhythm

by

OLOF LIPPOLD

Department of Physiology,
University College London WC1

The 8–12 Hz rhythmical waveform that can be recorded from the scalp of most human subjects when their eyes are closed does not originate in brain tissue. It is generated by physiological tremor in the extra-ocular muscles modulating the field set up by the standing potential of the eye.

SINCE the regular potential fluctuations that can be recorded from the human scalp were first described[1], the generally accepted view has been that the waves originate mainly in the occipital cortical neurones. The cells are pictured as beating in unison at a frequency of about 10 Hz whenever the cortex is "resting", that is, not receiving an input of patterned vision[2,3].

There are, however, a number of rather discordant features about the hypothesis. No convincing evidence has yet shown any "physiological function" for this alpha rhythm; 2–5 per cent of people never exhibit the waves and yet seem quite normal. In spite of the large amplitude of the waves (50 to 150 μV) and their widespread distribution over the head, there are no perceptual or motor concomitants that accompany their presence or absence. This is surprising in view of the much smaller size, on the scalp, of the evoked response (2–5 μV) which is presumably the electrical sign of perceptual activity within the grey matter. It is also disconcerting to find that the electrical indication of the onset of "rest" in the cortex is usually a ten-fold increase in the amplitude of a waveform.

There are phase-reversal points of the waves at the occipital regions of the skull, and their amplitude is at a maximum there; the site of origin was therefore postulated[4] to be in a dipole in the grey matter of each occipital lobe. This view is inconsistent, for it is well established that alpha waves in the frontal region, farther away from the supposed site of origin and smaller in amplitude, tend to lead the occipital waves by a variable interval, usually about 5 ms.

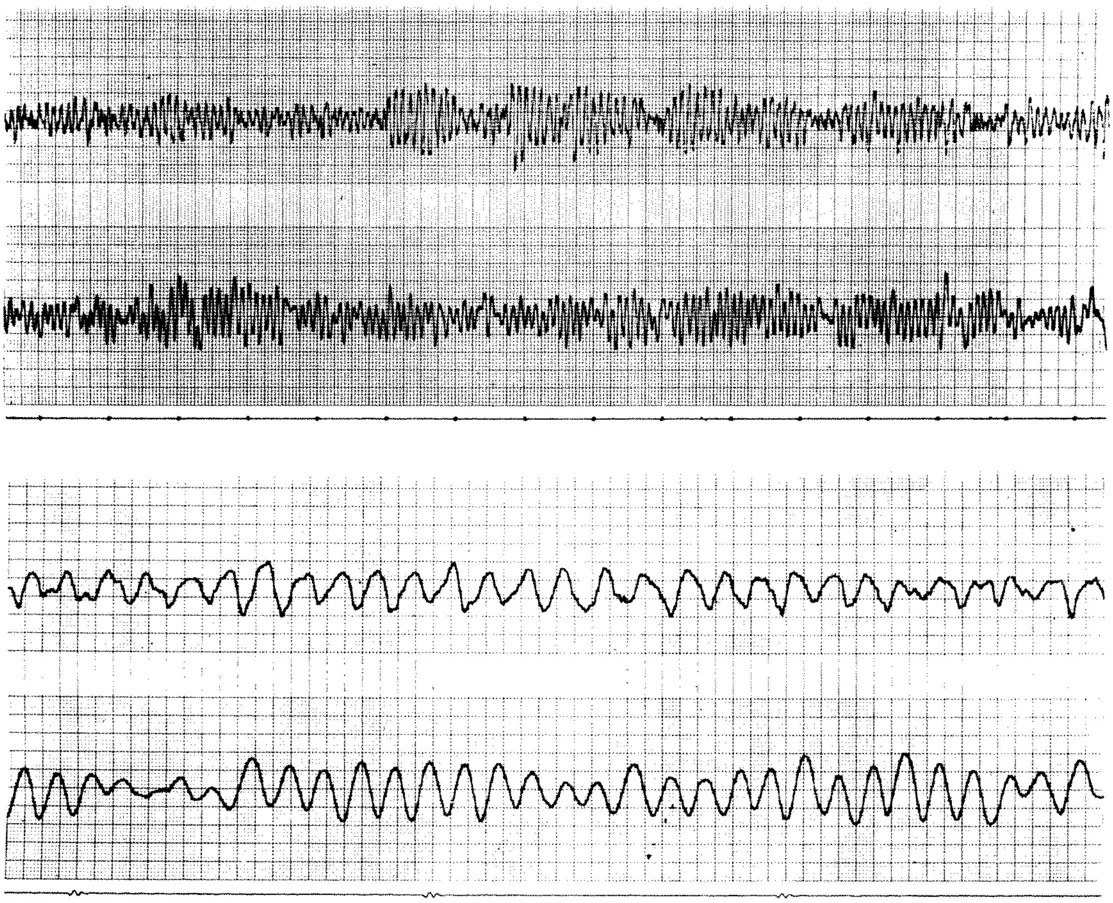

Fig. 1. Comparison between alpha waves recorded simultaneously with tremor waves from the forefinger, in a normal subject. Alpha waves were recorded as described by Lippold[12] and tremor by using a beam of light and phototransistor. Calibration per large square; alpha waves, 10 μV; tremor waves, 0·2 mm. Time, 1 s. Note, in the top pair of records, the similarity of general waveform (waxing and waning, and so on) and, in the bottom pair, the detailed similarity between individual waves.

New Explanation for Alpha Rhythm

The following alternative has been proposed[10]. The extra-ocular muscles, in common with all other skeletal muscles, have feed-back control; in common with other muscles, oscillation will take place at about 10 Hz in this servo when its loop gain exceeds unity[5]. In most people this condition tends to occur when the eyes are closed, or when there is no sharp image on the retina for the eye to be fixated on by feedback from the retina and the visual cortex.

The source of current for generating the waveform of alpha rhythm is the standing potential across the eye. It is conducted back into the interior of the cranium by the extra-ocular muscles which act as variable shunts producing an alternating 10 Hz field on the surface of the scalp whenever these muscles show physiological tremor.

The electrical record of alpha rhythm from the head closely resembles the mechanical record of the tremor of a limb (compare refs. 6 and 7). When both are recorded simultaneously from the same subject, they seem in general to correspond well; for example, the records look alike in response to loud sounds during sleep or anaesthesia[8]. Clearly, no constant phase relation exists between the two types of wave, nor is their frequency exactly the same[8] although the frequency spectrum has a similar form (see also Fig. 1). The frequency of tremor is slow in small children, gradually rising until the normal 10 Hz is reached in early adult life; the frequency of alpha waves has a similar variation with age[6,7]. In Parkinson's disease, tremor in muscle is characteristically at about 5/s. If the disease involves the eye muscles the predominant cortical rhythm is often at 5/s[9]. Further, subjects with both eyes enucleated have no alpha rhythm[2], although it must be stated that cortical blindness also leads to its disappearance (and subsequent reappearance if the sight is restored).

Anyone who has prominent alpha rhythm can make a simple observation to show that eye tremor can occur. A bright point-source of light is viewed against a completely dark field. If the gaze is now swept at a suitable speed (from top to bottom of the field of view in 1 s), vertically past the source, the resulting after-image can be examined. It will be found to be an approximately sinusoidal trace.

It has already been shown that local cooling of a limb slows its tremor because the delay in the servo-loop is then increased, as a result of lengthened muscle twitch time[5]. Cooling the orbit in man has a similar effect on the frequency of alpha rhythm[10], a finding which indicates that a similar servo-system could be in operation for the eye muscles.

Varying the Corneo-retinal Potential

Alteration of the illumination of the eye changes the value of this potential by a factor of up to three[11]. If alpha waves are indeed generated by the potential across the eye, the amplitudes of the former and the latter should co-vary.

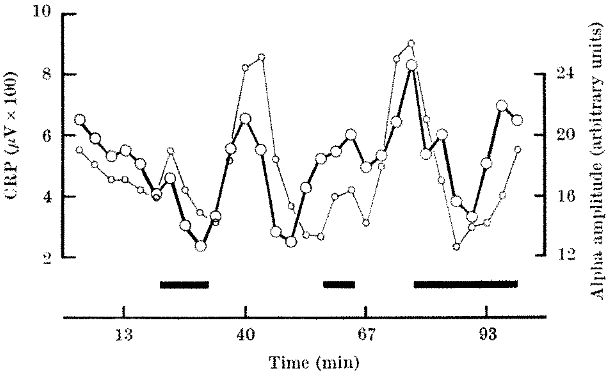

Fig. 2. Graph showing corneo-retinal potential (CRP, thin line) plotted with alpha amplitude (thick line) during the course of an experiment in which the former was varied experimentally by altering the intensity of ambient illumination. The CRP was measured by recording from electrodes in the inner and outer canthi while the gaze was rapidly switched between two fiducial marks by the subject (see ref. 11). Alpha amplitude was measured from occipital leads (O_2 to T_6 in the standard 10–20 system) using an Ediswan wave analyser. Black bars indicate that the subject was in darkness; at other times an X-ray viewing screen provided diffuse illumination. Note that the full range of CRP values occurs in both light and dark conditions; the results cannot thus be explained in terms of an effect of ambient illumination on retinal or cortical function. The alpha wave recordings were taken in all cases with eyes closed; 10 s periods were integrated. ($r = 0·55$; $t = 3·5$; $P < 0·01$.)

Fig. 2 shows the results of an experiment in which the value of the corneo-retinal potential was varied (thin line; small circles). Alpha wave amplitude was measured with an Ediswan analyser. There is an excellent correspondence between the magnitude of the corneo-retinal potential and the amplitude of the alpha waves ($r = 0·55$; $t = 3·5$; $P < 0·01$).

This experiment is, however, unsatisfactory because alpha rhythm tends to change in amount from time to time during a long experiment, as a result of the operation of factors such as attention, drowsiness or eye movements. (It is interesting to note that, if account is taken of this and mean amplitude per wave is computed, a better correlation can be obtained; for example, $r = 0·9$; $P < 0·0001$). The mean amplitude of alpha waves on the two sides of the head can be compared by a method I have already described[12]. The ratio of the alpha amplitude on each side can be compared with the ratio of the values of the corneo-retinal potential as the latter is experimentally varied. Fig. 3 gives the results of an experiment of this kind showing that the alpha amplitude depends, with a high degree of significance, on the value of the corneo-retinal potential on the same side of the head. This experimental design eliminates the difficulties (attention, drowsiness and so on) mentioned here, for they affect both sides similarly, and moreover it shows that the effect described cannot be mediated by nervous connexions from the retina because each visual cortex receives an equal innervation from the two eyes.

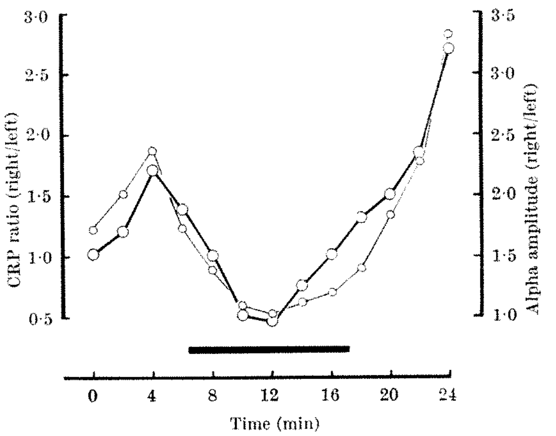

Fig. 3. Comparison between two sides of the head. The ratios between alpha amplitudes (thick line) on each side and CRP values (thin line) on each side are plotted. (Amplifiers, Tektronix type 122, T.C. = 0·02 s; H.F. cut at 50 Hz. Sanborn type 320 pen recorder.) Alpha amplitude measured by modification of method of Walter and Yeager[13] (area enclosed by peaks of waves, recorded at 20 mm/s, measured with a planimeter. Values are means of four periods of 5 s each). CRP measured for each eye separately as described in legend to Fig. 2. Illumination of each eye was altered independently by using light-tight goggles. Dark bar indicates time during which right eye was dark and left illuminated. At all other times left eye was dark and right illuminated. If values obtained on left side of the head only are plotted, they show that the intercept of the regression of y on x cuts the x-axis approximately at the value found for EEG amplitude with the eyes open.

When the corneo-retinal potential values are plotted against the alpha amplitude values for one side of the head only, the regression line cuts the alpha amplitude axis at a value that approximates to the mean EEG amplitude found when the eyes are open with fixated gaze. This indicates that the waveform of the EEG obtained with the eyes open does not originate from the corneo-retinal potential. It may represent either true cortical electrical activity, or it may be the attenuated electromyogram of other muscles in the head and neck region.

From the results of this very simple experiment, it can be concluded that occipital alpha waves are generated by the standing potential across the eyes. Other evidence shows that the likely mechanism involves some form of modulation of this potential by oscillation in the extra-ocular muscles (tremor) at about 10 Hz when there is no sharply focused image on the retina.

I thank Professor A. F. Huxley for many helpful discussions and for his encouragement. The MRC provided a grant for technical assistance.

A Paradox in the Interaction of the Gravitational and Electromagnetic Fields?

by

JAMES F. WOODWARD
WOLFGANG YOURGRAU*

Foundations of Physics,
University of Denver,
Colorado 80210

The assumption that the extent of the interaction of the electromagnetic and gravitational fields is fundamentally dependent on the frequency of the electromagnetic field is consistent with data on the deflexion of radiation by massive bodies.

RECENT experiments designed to test some consequences of the general theory of relativity have hinted that the theory may not be adequate to explain all the pertinent observations. Sadeh and others have found, for example, that the interaction between electromagnetic and gravitational fields departs markedly from the predicted behaviour. Further, all measurements of the deflexion of light by the Sun's gravitational field have given larger deflexions than expected. One fundamental assumption and two subsidiary requirements apparently suffice to account for the anomalous experimental results.

The fundamental supposition is that the extent of the interaction of the electromagnetic field with the gravitational field is functionally dependent on the frequency of the electromagnetic field. Two subsidiary requirements will be introduced at appropriate stages in the following discussion. It should be noted, however, that the stated assumption is not consistent with the general theory of relativity, which requires that the extent of the interaction of gravitational and electromagnetic fields be independent of frequency.

The chief manifestation of the interaction of gravitational and electromagnetic fields is the decrease of the velocity of light relative to Euclidean space–time coordinates. According to the general theory, the decrease is given by

$$c^2 = c_0^2\left(1 + \frac{2\Phi}{c_0^2}\right)$$

where c is the velocity of light in the gravitational field, c_0 that in field-free space, and Φ the potential of the gravitational field[1]. This formula is independent of the frequency of the light, and according to our fundamental assumption not fully correct. We postulate that c is linearly dependent on c_0; that is

$$c = c_0(1 + \alpha)$$

where α is some dimensionless function of ν and Φ; that is,

$$\alpha = f(\nu, \Phi)$$

On invoking the general theory as an approximate boundary condition, it follows that

$$\alpha = \frac{\beta(\nu)\Phi}{c_0^2}$$

where $\beta(\nu)$ is a function determined by the experimental data from the deflexion of light in the Sun's gravitational field and those of Sadeh *et al.*[2,3]. Thus

$$c = c_0\left(1 + \frac{\beta(\nu)\Phi}{c_0^2}\right)$$

Using this expression for c, we can derive the deflexion of a ray of light passing close to a massive body, as Einstein did in his 1911 paper[4]; we find that the deflexion δ is

$$\delta = \frac{2\beta(\nu)GM}{c_0^2 r_0} \tag{1}$$

where G is the constant of gravitation, M the mass of the (arbitrary) massive body, and r_0 the perihelion distance of the path of the light ray. For $\beta(\nu) = 2$, the above expression reduces to the δ predicted by the general theory. It is clear from our expression for δ that electromagnetic radiation of different frequencies will be deflected by different amounts in a gravitational field. This result, if true, provides a means of distinguishing between a gravitational field and an accelerated frame of reference. For suppose we observe the paths of two initially coincident light rays of different frequencies. If the paths of both rays remain the same, we have an accelerated frame of reference; whereas if they diverge, we have a gravitational field. Thus we reluctantly conclude that if the electromagnetic–gravitational interaction is frequency dependent, then the equivalence principle cannot be valid.

We now examine the experimental data provided by the various eclipse expeditions to see whether the assumption of the frequency dependence of the electromagnetic–gravitational field interaction is warranted. If the observed deflexion corresponds to that predicted by the general theory, then $\beta(\nu) = 2$, and the assumption of frequency dependence is unnecessary and unjustified. But if the observed deflexion is not the same as the prediction, then $\beta(\nu) \neq 2$, and the assumption of frequency dependence is necessary and justified.

Some of the results from the eclipse expeditions are very unreliable. In particular, the results of the 1936 and 1952 expeditions are virtually worthless for two reasons. First, in both cases almost all the stars in the star-field whose positions were measurable were more than three solar radii from the Sun. This means that the displacements were barely measurable and had large errors. The extrapolation from these measurements to a limb deflexion has a built-in error so large as to make the results completely unreliable. Second, in both cases there were serious technical deficiencies which serve to make the results even more untrustworthy. On the other hand, the results of the 1919, 1922, 1929 and 1947 expeditions are reliable and their errors not unreasonable.

Mikhailov has calculated the limb deflexion for all the eclipses, using a standard method of reduction of the data[5]. Because his method is more accurate in some cases than the method used by the original authors, we shall use his results exclusively. When one averages the results and the probable errors one obtains for the observed limb deflexion $\delta = 2{\cdot}02 \pm 0{\cdot}17''$. The prediction of the general theory does not even approach the lower limit of the probable error, so we conclude that $\beta(\nu) > 2$, and the assumption of frequency dependence is justified.

---

* Present address: Institut für Theoretische Physik, Universität Bern, Sidlerstrasse 5, 3000 Bern.

It is often claimed that the measurement of δ is based only on several observations and is therefore unreliable. This statement is misleading. It is true that only four eclipses have produced usable plates, but the determination of δ is based on the measurements of displacements of hundreds of stars and not just a few as the statement implies.

With one more subsidiary requirement (or boundary condition) a tentative explicit expression for $\beta(\nu)$ may be determined in the following manner. We stipulate: As ν goes to infinity, $\beta(\nu)$ goes to unity, or

$$\lim_{\nu \to \infty} \beta(\nu) = 1$$

This requirement may be reformulated in terms of the deflexion as

$$\lim_{\lambda \to 0} \delta = \frac{2GM}{c_0^2 r_0}$$

Analysis of the experimental data shows that for small values of the wavelength λ, δ is approximately proportional to $\lambda^{1/2}$. Thus we posit

$$\delta^2 = \left(\frac{2GM}{c_0^2 r_0}\right)^2 + K(r_0)\lambda + L(r_0)\lambda^2 \qquad (2)$$

where the coefficients $K(r_0)$ and $L(r_0)$ are functions solely of r_0. When $K(r_0)$ and $L(r_0)$ are determined (r_0 equal to the Sun's radius) from all the existing data (especially those of Sadeh *et al.*) that will be presented later on, we obtain

$$K(r_0) = 1{\cdot}65 \times 10^{-6}\ \text{cm}^{-1}$$
$$L(r_0) = 1{\cdot}75 \times 10^{-14}\ \text{cm}^{-2}$$

$\beta(\nu)$ may now be computed from equations (1) and (2), which gives

$$\beta^2(\nu) = \left(\frac{c_0^2 r_0}{2GM}\right)^2 (K(r_0)\lambda + L(r_0)\lambda^2) + 1 \qquad (3)$$

Using this relation for $\beta(\nu)$ and $\lambda = 4800$ Å (the average of the wavelength of maximum response for the photographic plates used), we obtain a value of δ which agrees with observation.

We now consider another test involving the interaction of the electromagnetic and gravitational fields. If the time taken for radiation to travel from one point to another changes as a function of time because of intervening gravitational fields, there will be a change in the frequency of the radiation such that

$$\frac{\Delta\nu}{\nu} = -\frac{\mathrm{d}\Delta\tau}{\mathrm{d}t}$$

where $\Delta\tau$ is the increased time of travel from the source to the observer. There are two factors that determine $\Delta\tau$: the path length and the velocity along the path. Consider the case of the electromagnetic radiation of a star passing close to the Sun. If either the general theory or our contention is correct, a time delay will occur, because both the path and the velocity of electromagnetic radiation are dependent on the gravitational fields present. There is, however, a significant distinction. The fractional frequency shift ($\Delta\nu/\nu$) will, according to the general theory, be the same for all frequencies and numerically very small, whereas on our assumption it will depend on the frequency of the radiation, because both path and velocity are dependent on frequency in a gravitational field. The predictions do differ markedly for long wavelengths, and we shall now derive the frequency shift supposing the interaction of the electromagnetic and gravitational fields to be dependent on frequency.

It follows from special relativity theory that, for a light ray,

$$\mathrm{d}r^2 + r^2\mathrm{d}\varphi^2 - c^2\mathrm{d}t^2 = \mathrm{d}s^2 - c^2\mathrm{d}t^2 = 0$$

that is,

$$\tau = \int \frac{\mathrm{d}s}{c} = \frac{1}{c_0}\int \frac{\mathrm{d}s}{(1+\alpha)}$$

Hence

$$\begin{aligned}\Delta\tau &\approx \frac{1}{c_0}\int (1+\alpha)\mathrm{d}s - \frac{s_0}{c_0} \\ &= \frac{1}{c_0}(s-s_0) + \frac{\beta(\nu)GM}{c_0^3}\int \frac{\mathrm{d}s}{r} \qquad (4)\end{aligned}$$

where s_0 is the straight line from the source to the observer, s is the total path length, and ν is assumed to be sufficiently large to allow the approximation of c by c_0 in the $(1+\alpha)$ term. Equation (4) can be rewritten as

$$\begin{aligned}\Delta\tau &= \frac{1}{c_0}(s-s_0) + \frac{\beta(\nu)GM}{c_0^3}\int_{\theta_{\text{source}}}^{\theta_{\text{observer}}} \sec\theta\ \mathrm{d}\theta \\ &= \frac{1}{c_0}(s-s_0) + \frac{\beta(\nu)GM}{c_0^3}\Big[\ln(\sec\theta + \tan\theta)\Big]_{\theta_s}^{\theta_{\text{ob}}}\end{aligned}$$

where θ is the angle between the radius vector from the Sun's centre to the perihelion point on the path and the radius vector to a point on the path. We define

$$R_{\text{ob}} = \sqrt{r_{\text{ob}}^2 - r_0^2}$$

and

$$R_{\text{s}} = \sqrt{r_{\text{s}}^2 - r_0^2}$$

Then

$$\Delta\tau = \frac{1}{c_0}(s-s_0) + \frac{\beta(\nu)GM}{c_0^3}\left[\ln\left(\frac{r_{\text{ob}} + R_{\text{ob}}}{r_0}\right) + \ln\left(\frac{r_{\text{s}} + R_{\text{s}}}{r_0}\right)\right]$$

If $r_{\text{s}} \simeq R_{\text{s}}$ and $r_{\text{ob}} \simeq R_{\text{ob}}$, we get

$$\Delta\tau = \frac{1}{c_0}(s-s_0) + \frac{\beta(\nu)GM}{c_0^3}\ln\left(\frac{4r_{\text{ob}}r_{\text{s}}}{r_0^2}\right)$$

Further, it is easy to show that

$$s \simeq s_0 + r_{\text{e}}\left(\frac{1}{\cos\delta} - 1\right)$$

where r_{e} is the distance from the perihelion point of the path to the observer. As a result,

$$\Delta\tau \simeq \frac{r_{\text{e}}}{c_0}\left(\frac{1}{\cos\delta} - 1\right) + \frac{\beta(\nu)GM}{c_0^3}\ln\left(\frac{4r_{\text{ob}}r_{\text{s}}}{r_0^2}\right)$$

Differentiating this equation with respect to time, we arrive at

$$\frac{\mathrm{d}\Delta\tau}{\mathrm{d}t} = -\frac{r_{\text{e}}}{c_0}\left(\frac{\sin\delta\ \dfrac{\mathrm{d}\delta}{\mathrm{d}t}}{\cos^2\delta}\right) - \frac{2\beta(\nu)GM}{c_0^3 r_0}\ \frac{\mathrm{d}r_0}{\mathrm{d}t}$$

Because in our case we are interested in $\delta < 1°$, $\sin\delta \simeq \delta$, and $\cos^2\delta \simeq 1$, this reduces to

$$\frac{\Delta\nu}{\nu} = -\frac{\mathrm{d}\Delta\tau}{\mathrm{d}t} = \frac{\delta r_{\mathrm{e}}}{c_0}\frac{\mathrm{d}\delta}{\mathrm{d}t} + \frac{\delta}{c_0}\frac{\mathrm{d}r_0}{\mathrm{d}t}$$

But

$$\frac{\mathrm{d}\delta}{\mathrm{d}t} = \frac{\delta}{r_0}\frac{\mathrm{d}r_0}{\mathrm{d}t}$$

so

$$\frac{\Delta\nu}{\nu} = -\frac{\mathrm{d}\Delta\tau}{\mathrm{d}t} = \frac{\delta}{c_0}\frac{\mathrm{d}r_0}{\mathrm{d}t} + \frac{r_{\mathrm{e}}\delta^2}{r_0 c_0}\frac{\mathrm{d}r_0}{\mathrm{d}t}$$

The term in δ^2 represents the change in ν caused by the change in time lag resulting from the increase in path length, and the term in δ represents the change in ν resulting from the velocity variation along the path. This result differs from that of the general theory chiefly because it treats $\beta(\nu)$ as a function of ν, while in the general theory $\beta = 2$ for all frequencies.

We now consider an experiment carried out by Sadeh *et al.*[2], where the apparent frequency shift for the 21 cm absorption line of Taurus A was determined when it passed close to the Sun on June 15, 1967. (The experiment was repeated in 1968 and yielded essentially the same results as those described below.) According to the general theory,

$$\frac{\Delta\nu}{\nu} = \frac{4GM}{c_0^3 r_0}\frac{\mathrm{d}r_0}{\mathrm{d}t}$$

leading to a prediction of $\Delta\nu$ for the 21 cm line that is three orders of magnitude smaller than that observed.

To determine the prediction based on our fundamental assumption, we first determine $\beta(\nu)$ for $\lambda = 21$ cm from equation (3) by substituting the Sun's radius for r_0 and the previously given values of $K(r_0)$ and $L(r_0)$. The outcome is $\beta(\nu) = 1{\cdot}39 \times 10^3$. The maximum value of $\Delta\nu$ may be computed using this value of $\beta(\nu)$, $r_0 = 3{\cdot}48 \times 10^{11}$ cm (which corresponds to the angular distance 1·25° from the Sun's centre), and $\mathrm{d}r_0/\mathrm{d}t = 2{\cdot}04 \times 10^6$ cm s^{-1}, giving $\Delta\nu_{\max} = 121$ Hz. This is in good agreement with the observed maximum value of about 150 Hz.

Another recent experiment that supports the assumption of the frequency dependence of the electromagnetic–gravitational interaction has been performed by Sadeh *et al.*[3]. They determined the relative rate of two caesium clocks as one of the two clocks was moved in successive steps from North Carolina to Nova Scotia. These authors demonstrate that no current theory can explain the observed frequency shift.

In our context it is worth considering the gravitational redshift that arises from the oblateness of the Earth. The expression for this effect is

$$\frac{\Delta\nu}{\nu} = \frac{GM}{c^2}\left(\frac{\Delta r}{\bar{r}^2}\right)$$

where $\bar{r}$ is the average of the distances from the centre of the Earth to two points on its surface and Δr is the difference between these distances. The approximate values of $\bar{r}$ and Δr corresponding to the maximum value of $\Delta\nu/\nu$ observed are $6{\cdot}37 \times 10^8$ cm and $2{\cdot}5 \times 10^5$ cm respectively. Positing that c is roughly the same as c_0 (as suggested by the general theory) and computing $\Delta\nu/\nu$, we obtain a value about one order of magnitude smaller than the observed value. But the assumption $c \simeq c_0$ for $\nu \simeq 1$ Hz (the condition realized in the experiment) is fallacious. Instead, we must use

$$c = c_0\left(1 + \frac{\beta(\nu)\Phi}{c^2}\right)$$

When $\beta(\nu)/c^2$ is computed for $\nu = 1$ Hz, it is seen to be equal to $1{\cdot}10 \times 10^{-11}$ s^2 cm^{-2}. Substituting this value, along with the values of other required quantities, in the equation for $\Delta\nu/\nu$, we arrive at $\Delta\nu/\nu \simeq 3 \times 10^{-12}$, which is in good agreement with the value experimentally obtained by Sadeh.

Sadeh *et al.*[6] have continued a search for novel effects capable of changing the frequency of a spectral line by measuring the times of arrival of pulses from pulsar CP 0950. According to a hypothesis advanced earlier by Sadeh, a cumulative delay of the pulse arrival time should have appeared as the line of sight to CP 0950 passed close to the Sun. A transient retardation was indeed observed, but no cumulative retardation, contrary to Sadeh's prediction.

On brief reflexion it becomes clear that our conjecture predicts a transient retardation, similar to the prediction of the general theory, but larger. No cumulative effect, however, is predicted. Hence our theory agrees with the experimental results.

Markowitz[7] attempted to determine whether the frequency of a radio wave was decreased, according to the hypothesis of Sadeh, as it passed through the Earth's gravitational field. The crucial aspect of this experiment is that the determination is independent of the rates of the clocks used to observe the frequency of the wave. The prediction of our theory is that the relative rates of the clocks would be different because of the previously described gravitational effect, but that the frequency of the signal carrier-wave itself would merely be negligibly redshifted because of its high frequency (100 KHz). Markowitz's results, which showed that the carrier-wave is only minutely shifted, agree with our theory. His findings, however, do not invalidate Sadeh's results, because the relative rates of the clocks as a function of the local gravitational field were not examined at all. We therefore infer that Markowitz's data preclude the validity of Sadeh's conjecture, but are not at variance with our theory.

Warner and Nather[8], considering the time-delay between pulses in the yellow and ultraviolet from NP 0532, have reached the conclusion that the speed of light is independent of frequency. There are, however, several variable stars[9] which have time-delays of the order of 10^2 s. We therefore feel that it would be premature to reject the frequency dependence theory on the basis of Warner and Nather's results.

It should be noted that our calculations have used a Euclidean metric. The reason is that if one adheres to a geometrical representation of the gravitational field, the frequency dependence requires the introduction of an infinite number of superimposed space–times of varying metrics. Physically, this interpretation is somewhat less than desirable. It is possible, however, to use the Schwarzschild metric, in which case the deflexion and fractional frequency shift equations must be multiplied by a factor of two and the values of the coefficients $K(r_0)$ and $L(r_0)$ must be suitably adjusted to fit the experimental data. But the choice of metric has no bearing on any of our conclusions, because no single frequency-independent metric can be used as a basis for explaining all the experiments we have discussed.

We thank A. J. van der Merwe for criticism and advice.

The Nature of Pulsar Radiation

by

F. PACINI*

Pulsar radiation may be due to particles which gyrate while moving in bunches along curved orbits. If emitted by electrons, the pulses should come from near the speed of light circle; if emitted by protons, they should arise within a few stellar radii of the underlying star.

THE amount of energy released by a neutron star in the form of pulsed radiation seems to be a small fraction of the total loss of rotational energy. An understanding of the radiation mechanism, however, would provide information about the magnetosphere of the neutron star and about general pulsar electrodynamics. Our purpose here is to discuss the nature of the radiation and to give some estimates for the density, energy and amount of correlation in the emitting plasma.

We find that the coherent radio emission could arise from the relativistic motion of bunches of particles along curved orbits; these orbits possibly may be identified with the field lines which emanate from the magnetic poles of a rotating neutron star and are able to cross the speed of light cylinder (open field lines). The incoherent optical and X-ray emission from NP 0532 can be produced by a simultaneous gyration of the particles around the same open field lines. Also, the radiation process should take place close to the speed of light distance $r = c/\Omega$ (Ω is the pulsar angular frequency) if it is caused by electrons. The pulses can, however, be emitted at a few stellar radii if the radiating particles are protons.

Particular pulsar models in which bunches of particles radiate in the radio band by virtue of the curvature of their orbits have already been discussed. Following a suggestion by Gold[1], Bertotti *et al.*[2,3] have considered the possibility that the pulses arise close to the speed of light distance, where the orbits should have a radius of curvature $\rho \sim c/\Omega$. As an alternative, Radhakrishnan[4] and Komesaroff[5] have suggested that the radiation is produced close to the star by particles moving away from the magnetic poles along the curved field lines. As the curvature of the lines of force at a distance r from the star is

$$\rho \sim \left(r\frac{c}{\Omega}\right)^{1/2}$$

these two alternatives are based upon the same idea; the difference is whether the curvature is evaluated close to the star or close to the speed of light distance.

We shall first show that the curvature of the field lines can be responsible only for the radio and not for the optical and X-ray emission from NP 0532. It is well known that the power radiated per unit frequency by a charge e moving relativistically

$$\left(\gamma = \frac{E}{mc^2} \gg 1\right)$$

along an orbit with radius of curvature ρ is given by

$$I(\nu) \sim \frac{1}{2\pi}\frac{e^2}{c}\left(\frac{\rho}{c}\right)\gamma\left(\frac{\nu}{\nu_{cr}}\right)^{1/3} \quad (\text{for } \nu < \nu_{cr}) \tag{1}$$

and reaches a maximum just below the critical frequency

$$\nu_{cr} \sim \frac{1}{2\pi}\frac{c}{\rho}\gamma^3 \tag{2}$$

The emission of frequencies up to about 10^{18} Hz at a rate of about 10^{36} erg s^{-1} would typically require $\gamma \sim 10^5$. Also the total number nV of radiating particles should be such that

$$\frac{1}{2\pi}\frac{e^2}{c}\left(\frac{c}{\rho}\right)\gamma nV \sim 10^{18}\ \text{erg s}^{-1}\ \text{Hz}^{-1} \tag{3}$$

Thus $nV \sim 10^{40} - 10^{41}$ particles (depending on where the emission occurs and the relevant value for ρ). For every conceivable value V of the emitting volume, this yields an implausibly high density of very energetic particles.

One is then led to consider the possibility that the optical and the X-ray emissions from NP 0532 are due to normal synchrotron radiation. Because the optical and radio pulses are simultaneous (at least within a small fraction of a millisecond), they should involve the same emitting region and, probably, the same particles. We shall consider a radiation scheme where the individual particles gyrate (with a small pitch angle) while also moving in bunches along the curved field lines. As we shall see, the observed brightness temperature in the radio band requires bunches much larger than the Larmor radius. One can therefore examine separately the two components of motion and the two radiation process. Also the emission connected with the gyration will be incoherent.

Pulses from the Speed of Light Distance

We examine first the case in which the pulses are emitted close to the speed of light distance and are connected with the kinematics described previously. When this possibility was considered earlier, Bertotti *et al.*[2,3] assumed for the magnetic field $B_\perp \sim B \sim 10^6$ G. This value close to the speed of light distance

$$r = \frac{c}{\Omega} = 1{\cdot}5 \times 10^8 \text{ cm}$$

corresponds to a surface strength around 3×10^{12} G (as deduced from the rate of slowing down). It is clear, however, that the optical and the radio pulses will coincide in timing and (roughly) in pulse width only if the radiating particles move with a small pitch angle θ around those field lines which we see during the radio pulse. If τ is the pulse width and P is the period, the requirement is $\theta \lesssim \tau/P$. In the case of NP 0532, the main pulse has a width $\tau \sim 250$ μs and period $P \sim 33$ ms; this implies $\theta \leq 5 \times 10^{-2}$ and $B_\perp \leq 5 \times 10^4$ G.

We note that, because of the additional contribution from the distribution of pitch angles, the optical pulse should still be wider than the radio pulse. This agrees with the observations.

Shklovskii[6] has recently used the theory of synchrotron reabsorption and the position of the low frequency cutoff in the optical spectrum of NP 0532 to determine $B_\perp$ in the emitting region. Assuming for this region a linear size $l \sim 10^7$ cm, he finds $B_\perp \sim 3 \times 10^3$ G which corresponds to a pitch angle $\theta \sim 3 \times 10^{-3}$. The observed optical and X-ray emission can then be due to electrons with an energy from ~ 100 MeV up to several BeV and a total density about 10^{14} cm^{-3}. Also, at the speed of light distance, the energy density in relativistic particles is almost as large as the electromagnetic energy density.

The value determined by Shklovskii is less than our upper limit and supports the idea of emission close to the speed of light distance. If indeed the pulses were emitted close to the star, the magnetic field would be stronger and the emitting region smaller, so synchrotron reabsorption would set in at frequencies much higher than observed. We stress, however, the assumption of an electron emission; as we shall see later, the position of the cutoff can be consistent with an emission close to the star if the emission is due to protons. For the moment, however, we shall accept the idea that the emission is due to electrons and occurs at a distance of order c/Ω.

† On leave of absence from Institute of Theoretical Astronomy, University of Cambridge (present address).

If the radio emission at frequency ν is attributed to bunches of particles moving along the field lines with velocity corresponding to a Lorentz factor γ_{bunch}, then the following condition should be satisfied

$$\frac{1}{2\pi}\frac{c}{\rho}\gamma^3_{\text{bunch}} \gtrsim \nu \tag{4}$$

The number of particles N contained in a bunch must be

$$N \gtrsim \frac{kT_{\text{b}}}{mc^2\gamma_{\text{bunch}}} \tag{5}$$

in order to achieve a sufficiently high brightness temperature T_{b}. The maximum dimension along the line of sight of a bunch which emits coherently at frequency ν is c/ν. In the case of a quasi-spherical bunch, this, together with relation (5), sets a lower limit to the particle density n.

If the individual particles have velocity v and pitch angle θ, then for the bunch

$$\gamma_{\text{bunch}} \leq \left(1 - \frac{v^2}{c^2}\cos^2\theta\right)^{-1/2} \tag{6}$$

which means roughly $\gamma_{\text{bunch}} \lesssim \min(\gamma_{\text{particles}}, \theta^{-1})$.

Coherent emission is observed up to about 10^9 Hz, corresponding to a wavelength of about 30 cm, so one requires $\gamma_{\text{bunch}} \gtrsim 300$. Some bunching should also exist with typical size $\lesssim 30$ cm. Because the brightness temperature of NP 0532 in the radio region is about 10^{26} K (again assuming an emitting region 10^7 cm), relation (5) gives $N \sim 10^{14}$. Note that there is no energy problem in the formation of these bunches—the kinetic energy of the particles exceeds the electrostatic energy. A volume $\sim$(wavelength)^3 and a density of 10^{14} cm^{-3} corresponds to a total number of particles per bunch in excess of 10^{18}. There would then be the required degree of coherence even if only 10^{-4} of the electrons present in the bunch had sufficiently small pitch angle to yield $\gamma_{\text{bunch}} \gtrsim 300$. It is also possible that the degree of coherence is reduced by the presence of positive charges in the bunch. (This would not affect the incoherent optical and X-ray emission.) The occasional presence of very strong radio pulses from NP 0532 (ref. 7) can be attributed to bunches containing a number of particles exceeding the typical value of 10^{14}. In the case of the Crab pulsar, this is energetically possible.

The spectrum of the pulsar radio emission should be determined chiefly by the degree of coherence at a given frequency, that is, by the spectrum of correlations in the plasma. In what follows we shall, however, use $N \sim 10^{14}$ as a typical coherence factor and we shall evaluate the density of the particles responsible for the radio emission by using equation (1). If we assume $\gamma_{\text{bunch}} \sim 300$, $N \sim 10^{14}$, $c/\rho \sim \Omega \sim 200$ s^{-1}, an emitting volume $V \sim l^3 \sim 10^{21}$ cm^3, and a luminosity 10^{31} erg s^{-1} over the radio band $\sim 10^9$ Hz, we have

$$\frac{1}{2\pi}\frac{e^2}{c}\left(\frac{c}{\rho}\right)^2 \gamma^4 n V N \sim 10^{31} \text{ erg s}^{-1} \tag{7}$$

This yields $n \sim 10^{12} - 10^{13}$ cm^{-3}.

We note that the formal rest plasma frequency exceeds the frequency of the radio waves. Because of the very strong magnetic field, high energies, and important collective effects, it is, however, clear that the usual simple theory of reabsorption cannot be applied here.

The pulsed nature of the source should be a consequence of the fact that the particles involved in the emission occupy a limited sector of the magnetosphere. Unfortunately, present knowledge of pulsar electrodynamics and the configuration of the field close to the speed of light distance does not allow any prediction to be made regarding the pulse structure and the duty cycle.

In the case of NP 0532, the main narrow pulse is preceded at radio frequencies by a much wider precursor. The observations available at present[7] show that the precursor is ~ 100 per cent linearly polarized while the main pulse seems to be much less polarized; and the precursor cannot be seen at optical and X-ray frequencies. We suggest tentatively that the precursor is due to protons streaming outwards along field lines different from those followed by the electrons[8]. If the Lorentz factor of the bunches containing an excess of protons also satisfies relation (4), then there would be proton radiation at the radio frequencies as well as the electron radiation previously considered; this is because the emission at radio frequencies depends on the curvature of the field lines and the Lorentz factor but not on the mass of the particles.

The different degree of polarization of the main pulse and the precursor can also be explained. It is well known that the radiation from charges moving along curved orbits is strongly polarized only close to or above the critical frequency. The observed difference in polarization between the main pulse and the precursor (if confirmed) could simply mean that, for the bunches, $\gamma_{\text{protons}} < \gamma_{\text{electrons}}$. In this case the proton radiation in the observed band could be closer to the critical frequency than the electron radiation and therefore more polarized.

If the acceleration in the near magnetosphere is chiefly electrostatic, one expects that the individual protons and electrons will reach about the same energy, that is, for the individual particles, $\gamma_{\text{protons}} \sim 10^{-3}\gamma_{\text{electrons}}$. In this case one should not expect any proton radiation in the optical or X-ray band. This might explain the absence of the precursor at high frequencies. The possibility of proton cyclotron or synchrotron radiation at very high radio frequencies or in the infrared is not worth consideration at present as the expected power output is very small.

Concerning the presence of an interpulse from NP 0532 (and from a few other pulsars) we simply remark that this could be due to a difference in the light travel time between two pulses emitted simultaneously from the two magnetic poles. (This would imply that the motion of the particles at $r \sim c/\Omega$ is such that we can see emission from both sides of the star.)

Finally, it is clear why only very fast pulsars are likely to emit optical or X-ray radiation. In the case of long period pulsars, the speed of light distance is much farther from the star and the local magnetic field strength at $r \sim c/\Omega$ is small so gyration therefore becomes less important. An emission spectrum with two peaks (one at radio frequencies due to the motion along the field lines, and the other at higher frequencies due to the gyration) would be a likely feature of most sources. One would expect the high frequency peak (proportional to B and therefore to P^{-3}) gradually to shift toward the infrared so that power emitted (proportional to B^2 and therefore to P^{-6}) gradually becomes negligible.

Pulses from Close to the Star

Komesaroff[5], following a suggestion by Radhakrishnan[4] has explored the alternative possibility that the pulses are emitted close to the star by bunches of particles moving away from the magnetic poles along the open field lines. As in the previous model, the curvature of the field lines produces the radio frequencies and the simultaneous gyration produces the optical and X-ray frequencies. An attractive feature of this model is the natural explanation for the duty cycle of the pulsars, because close to the poles the open field lines occupy only a small angular sector. This model can also account for certain features of the pulse shape and for the behaviour of polarization during the pulse. (We stress the implicit hypothesis that the field structure can be described by a simple dipole even close to the star.)

As we have already mentioned, however, the position of the low frequency cutoff in the optical spectrum of NP 0532 is not compatible with the idea of synchrotron radiation by electrons in the vicinity of the star. We wish to point out that this situation changes if the emission is due to protons. In this case the particles should have higher energies in order to produce optical and X-ray emission. In turn this permits a higher brightness temperature to be attained before self-absorption sets in.

To shorten our discussion, we give one set of parameters for radiation close to the star which appears to satisfy all the observational constraints.

Suppose that the emitting cone extends out to about five stellar radii (5×10^6 cm). The magnetic strength at this distance would be $B \sim 2 \times 10^{10}$ G, the field lines which eventually cross the speed cylinder would occupy a cone of about 10° and the diameter of the radiating area would be about 10^6 cm. By considerations analogous to those made earlier, one expects $B_\perp \lesssim 10^9$ G. It is then easy to use the formulae for synchrotron radiation and reabsorption (applied to protons) to find that it is possible to match the observed position of the low frequency cutoff in the optical spectrum.

The protons which radiate at optical and X-ray frequencies would have $\gamma \sim 30$ up to about 10^3 (energies up to about 1 erg). Assuming an emitting volume $(10^6)^2 \times (5 \times 10^6) \approx 5 \times 10^{18}$ cm^3, an output $\sim 10^{36}$ erg s^{-1} requires

$$\frac{e^2}{c}\left(\frac{eB_\perp}{m_p c}\right)^2 \gamma^2\, n\, V \sim 10^{36}\ \text{erg s}^{-1} \qquad (8)$$

that is, $n \sim 10^{17}$ cm^{-3}. For the anisotropic geometry of emission considered in this model, the total luminosity might be down by a factor of ten, that is, $L \sim 10^{35}$ erg s^{-1} and $n \sim 10^{16}$ cm^{-3}. This would correspond to an outward flux of energy in the form of relativistic particles $\sim 10^{38}$ erg s^{-1}, about the same as the overall energy requirements of the Crab Nebula. One must assume, however, that most of the energy is transferred to particles within only a few stellar radii.

Concerning the coherent radio emission, the radius of curvature of the relevant field lines at a distance $r \sim 5 \times 10^6$ cm from the star is 2×10^7 cm and therefore (from relation (4)) one should require $\gamma_{\text{bunch}} \gtrsim 200$. Because the brightness temperature of NP 0532 with an emitting region $(10^6)^2$ cm^2 would reach 10^{28} K, considerations similar to those made before require $\sim 10^{13}$ protons per bunch. The density of particles with pitch angle small enough to give $\gamma_{\text{bunch}} \gtrsim 200$ should be $\sim 10^{13}-10^{14}$ cm^{-3}.

We note that, if electrons are present, they would not affect the discussion of self-absorption because of the very high gyrofrequency. No simple solution can be offered, however, to explain the undetectability of electron radiation, unless the electrons move only along field lines which we are not able to see. Similarly, there is no simple explanation for the presence of a precursor in the radio pulse and its absence in the optical and X-ray band. One could instead explain the presence and the position of the interpulse if the geometry of the emission was such that the second pole also points (at some phase of each revolution) in a direction close to the observer. It is very likely in this case that one of the two poles will usually be better directed toward us than the other, so as to give rise to the main pulse. The emission from the pole which is less well directed would have to arise farther away from the stellar surface in order to be visible to us. Because of the smaller light travel time, the precursor would be expected to arrive sooner than halfway between two successive main pulses, and this is indeed the case for NP 0532.

Finally, we note that at the energies involved, nuclei would be completely stripped of surrounding electrons. This implies that similar considerations also apply to radiation from heavier nuclei, the maximum brightness temperature for incoherent synchrotron emission scaling as $m^{3/2}\,Z^{-1/2}$.

Pulsar Electrodynamics

As we have seen, the main advantage of explaining pulsars by radiation from close to the star is the simple interpretation of the duty cycle. One must assume, however, that we are seeing only radiation from protons (or heavy nuclei). If the radiation process occurs close to the speed of light distance, one can account for many features of the observations, but our present knowledge of pulsar electrodynamics is insufficient to explain the small duty cycle. In both cases, however, the pulsar radiation can be understood only if in the near magnetosphere (at distances $r \lesssim c/\Omega$) there are particles with Lorentz factors of about 10^3 and densities 10^{14}–10^{16} cm^{-3}. Some particles of higher energy should also be present. These high densities and energies would have important implications for the more general theory of pulsar electrodynamics.

We have already noted that, if the radiation is due to protons (within a few stellar radii) the energy loss associated with the outwards motion of these particles is about 10^{38} erg s^{-1}. The production of high energy particles (protons and, presumably, electrons) would then be chiefly a local phenomenon close to the star. The slowing down of the stellar rotation would also be related more to this ejection of particles than to the electromagnetic torques discussed in the past[8-10]. Well before the critical distance c/Ω, the particle energy density would indeed exceed the energy density in the electromagnetic field.

On the other hand, if the pulses are emitted at $r \sim c/\Omega$, the energy densities of the particles and the fields would be almost of the same order. If, at $r > c/\Omega$, the field decreases as $1/r$ (refs. 8 and 9) and the average energy per particle does not change appreciably, one could maintain this equipartition over the entire Crab Nebula.

At $r \sim c/\Omega$ one should expect also a deformation of the field lines with respect to the pure dipole case. We recall that, in a pure dipole field, the slowing down can be described by

$$\dot{\Omega} \propto \Omega^n \qquad (9)$$

where $n = 3$. The observed value $n \sim 2{\cdot}2$ (ref. 7) supports the notion of a distortion in the radial direction. (If fewer particles are ejected from old pulsars, one might expect that for them the index n will be closer to three.)

Finally, it is well known that the Crab Nebula contains some electrons with an energy up to about 10^{14} eV. Ostriker and Gunn[10] have shown how energies of this order can be reached when the particles move in the low frequency radiation field generated by the rotation of a neutron star with an inclined dipole field[11]. The basis of this acceleration is the existence at $r > c/\Omega$ of an electric field $E = B$ over a distance $\sim c/\Omega$. If the particles move in phase with the field, they would reach energies $E \times c/\Omega$ ($\sim 10^{14}$ eV in the Crab). The very high densities inferred from the pulsar radiation suggest, however, that only a few particles will be able to attain the maximum energy. The energy spectrum of the electrons in the Crab Nebula is therefore likely to arise from a combination of accelerations in the near and in the far magnetosphere.

We thank Dr A. Cavaliere, T. Gold and E. E. Salpeter for discussions. During the course of this work, one of us (F. P.) was supported by the NSF and by the ONR.

LETTERS TO THE EDITOR

PHYSICAL SCIENCES

Hyperon Star Matter

HYPERON stars are neutron stars with a superdense core ($\rho > 10^{15}$ g cm^{-3}) consisting chiefly of baryons and heavier resonances. The equation of state for such a multicomponent system is determined by the elementary particle spectrum. This spectrum is known to be exponential up to about 2 GeV (ref. 1) For higher energies there is a worsening of experimental knowledge. We assume the exponential behaviour to continue (ref. 1 and unpublished work of Krzywicki) beyond 2 GeV, and take into account the fermions only, which yields in the low temperature limit the Hansen results[2]. Then the equation of state becomes temperature dependent because the heaviest components are partially nondegenerate. If the core of the hyperon star is in general relativistic thermal equilibrium, the polytropic index of the relation between pressure and total density (including kinetic energy) proves to be negative. As a consequence the velocity of sound in the radial direction, defined by

$$v_s = \sqrt{\frac{dP}{d\rho}},$$

decreases towards the centre instead of exceeding the velocity of light[3]. Under the additional hypothetical supposition that the mass spectrum remains exponential up to infinity (infinite energies), in hyperon stars the temperature cannot exceed a limiting temperature of $T_0 = 2 \times 10^{12}$ K and the time component g_{00} of the metric tensor of space-time cannot become zero.

For any gas component the conditions of thermal equilibrium in general relativity as given by Balasz[4], Ebert[5] and Ehlers (ref. 6 and a private communication) are

$$\gamma = \frac{\mu + mc^2}{kT} = \text{const}; \qquad T \cdot \sqrt{g_{00}} = \text{const} \qquad (1)$$

throughout the star, μ being the chemical potential, and m the mass of a hyperon of a single gas component. To obtain the equation of state we need the solutions of the relativistic Fermi-integrals, which were established by the quick numerical programme of W. D. Bauer (unpublished).

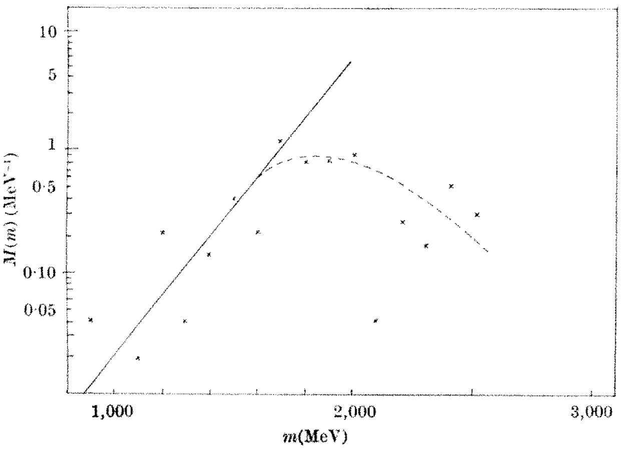

Fig. 1. The fit of the approximation of smooth abundance distribution to the experimental data.

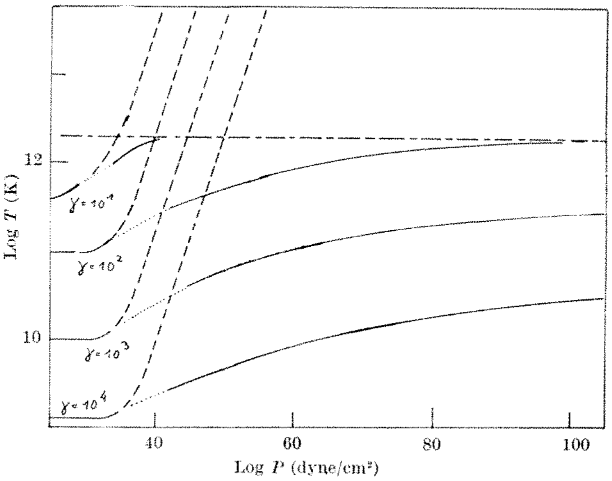

Fig. 2. The internal structure of hyperon stars.

If we neglect the virial interaction between the particles of a multicomponent system but take account of the baryon number and energy conservation, we can apply the local equilibrium condition

$$\gamma = \text{const}, \quad T = \text{const} \qquad (2)$$

for every single component. Eventually one can take into account the strong interaction between neighbouring particles by considering them as one new particle ("molecule"). For the level distribution of the components (of the multicomponent gas) Hansen's calculation proved that for high densities the antiparticles as well as the bosons diminish relative to the increase of fermions, which led us to our restriction to baryonic fermions.

The approximation of the smooth abundance distribution (the number of different hyperons per mass interval):

$$H(m) = \exp\left(\frac{mc^2}{kT_0} + 52\right), \quad T_0 = 2 \times 10^{12}\,\text{K} \qquad (3)$$

fits the experimental data well up to 2 GeV (Fig. 1). For higher energies the particle spectrum is poorly known. The parameter T_0 is almost identical with the "highest possible temperature in nature" as proposed by Hagedorn[1]. Using equations (3) and the relativistic Fermi-integrals and integrating over the whole hyperon spectrum, we obtain the equation of state of the multicomponent gas to be found in the interior of hyperon stars.

The internal structure of hyperon and (for comparison) of neutron stars is implicitly given by Figs. 2 and 3, because (because of conditions (1)) each γ-line has as a parameter the radius coordinate of a single star (if the general relativistic differential equations, connecting ρ, T, P, r, $M(r)$ have been solved).

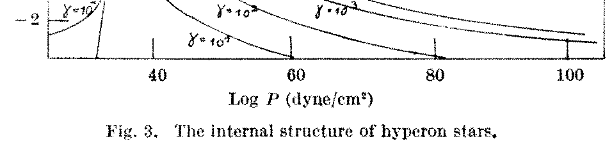

Fig. 3. The internal structure of hyperon stars.

From Fig. 2 it can be seen that in the centre of hyperon stars the temperature cannot exceed T_0 in contrast to the conventional neutron stars.

For $T \to T_0$ the matter curdles, the total rest mass energy grows faster than the kinetic energy. It can be seen from Fig. 3 that the exponent of the relation between P and ρ is less than 1 for every star, which indicates a negative polytrope index. In contrast to a pure neutron star, the log (P/ρ)-lines are dependent on γ which is due to the fact that the heaviest hyperon components are not degenerate.

In our multicomponent stars the velocity of sound in the radial direction $v_s = \sqrt{\frac{dP}{d\rho}}$ decreases with increasing density (towards the centre of the star) instead of surpassing the velocity of light as some authors[3] have proposed. Even if the density has a singularity at the centre, the time component g of the metric tensor remains nonzero.

Astrophysical Implications of the Continuity Equation Plasma Oscillation

THERE are several periodic astrophysical phenomena which may involve the periodic generation of pulses of charged particles[1-5]. The periodicity of pulsars, for example, is usually attributed to a dynamical origin[6], but may instead have a plasma-physical origin. A characteristic feature of the continuity equation oscillation discovered recently is the periodic production of pulses of ions and electrons from the oscillating region. This oscillation arises from the time delay associated with the transit of charged and neutral particles across the oscillating region, which brings about a relaxation oscillation of the charged particle number density within it[7-9]

An appropriate physical model incorporating transit time delays has been analysed, and yields the continuity equations which follow (ref. 7 and my unpublished work).

$$\dot{n} = \hat{n}_e n(\sigma v)_{ne} - n_e n(\sigma v)_{ne} \qquad (1)$$

$$\dot{n}_e = -\hat{n}\, n_e(\sigma v)_{ne} + n n_e(\sigma v)_{ne} \qquad (2)$$

where $\hat{n}_e$ and $\hat{n}$ are, respectively, the time averaged electron and neutral number density in the oscillating region. $(\sigma v)_{ne}$ is the ionization rate parameter for electron-neutral ionization. It has been shown that the electron and neutral number densities oscillate with a frequency that is approximately

$$\nu = \frac{\sqrt{\hat{n}_e \hat{n}}\ (\sigma v)_{ne}}{2\pi}\ \text{Hz} \qquad (3)$$

when the peak-to-peak amplitude of $n_e(t)$ is small compared with its maximum value.

In an astrophysical context, the second terms of the right-hand side of equations (1) and (2) represent, respectively, the instantaneous rate at which neutrals are lost, and charged particles are produced, by electron-neutral impact ionization. My unpublished work shows that a consideration of the divergence term will yield the first terms appearing on the right-hand side of equations (1) and (2), when time delay effects are important. Equations (1) and (2) have long been known to possess periodic solutions[10-12]. The waveform of $n_e(t)$ is shown in Fig. 1 for a percentage ionization $\delta = 0{\cdot}01$, and for four values of the amplitude index $\eta = \hat{n}_e/n_{eo}$. The characteristics of the waveforms of $y(t)$ for $\eta \leq 0{\cdot}25$ are particularly suggestive of pulsar waveforms.

Comparison of the theory based on equations (1) and (2) with experimental observations has been reported elsewhere[8,9]. Data were taken which confirmed the functional dependence of frequency on the square root of the product $\hat{n}_e \hat{n}$ given by equation (3) (refs. 8 and 9). The frequencies observed in these experiments varied from 87 Hz to 100 kHz, a range of more than 10^6 in the density product $\hat{n}_e \hat{n}$. The waveform of the ion current flowing from the discharge was measured by a suitable collector. A representative sample of the data showing ion pulses from the discharge is given in Fig. 2 for the various background pressures of deuterium gas shown in Table 1. In each photograph, the time increases from right to left, and the zero level is the baseline between pulses. The pulses usually became broader and less regular as the

2h	$2{\cdot}65 \times 10^{-5}$	25·0	0·0390	5·0	10

neutral density was increased. The ion efflux in Fig. 2 shows such features as periodic interpulses (Fig. 2*b*), periodic fine structure on the individual peaks (Fig. 2*f*), and other details suggestive of pulsar waveforms. The sharp, narrow peaks between broad, flat minima of these waveforms are in good qualitative agreement with those predicted theoretically in Fig. 1.

The oscillation frequency was measured as a function of time, and is shown in Fig. 3. The frequency did not vary by more than a few per cent over a duration of 200 min, consistent with the precision with which n_e and n could be controlled in the experimental apparatus. This stability of the 28 kHz pulses for 200 min implies that the frequency did not change more than a few per cent over about $3{\cdot}3 \times 10^8$ individual pulses. This would imply a similar degree of stability for about 10 yr in an astronomical object with a period of one second.

Observations were made with a pair of collimated photomultipliers placed at various axial and radial positions. It was found that the plasma was oscillating in phase, with a single frequency. The single frequency was somewhat surprising in view of the approximately ten-fold variation in electron number density (and hence in the product $\bar{n}_e\bar{n}$) from the centre to the edge of the plasma. Apparently the fast-moving electrons serve as an averaging and synchronizing mechanism, and permit a region with large variations in $\bar{n}_e\bar{n}$ to oscillate as a macroscopic structure with a single eigenfrequency.

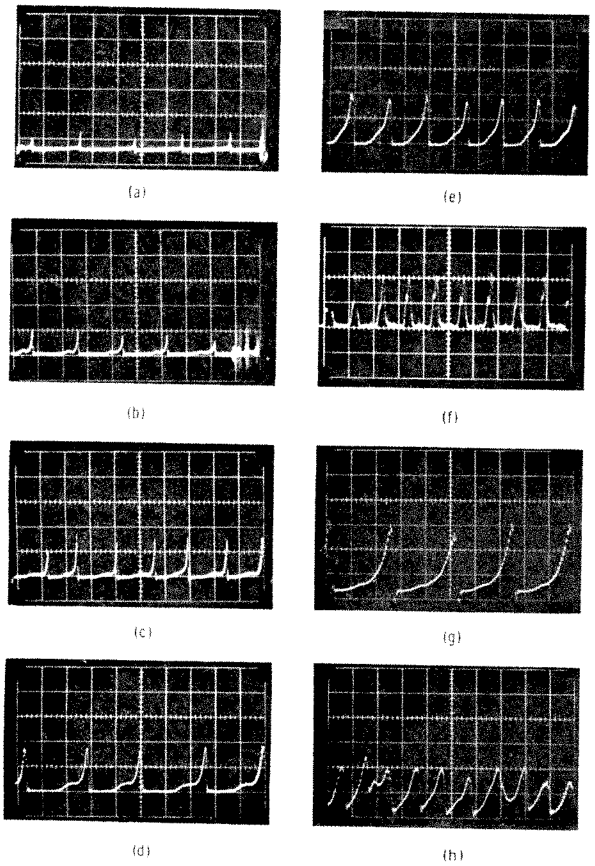

Fig. 2. Experimentally measured waveforms of pulsed charged particle flux from a discharge subject to the continuity equation oscillation. The experimental conditions for each case are listed in Table 1. All runs shown were with deuterium gas, at a maximum magnetic field of $B_{\max} =$ 1·0 Tesla. The charged particle number density is proportional to anode current. The zero level is the baseline, or lowest excursion, of the trace between pulses. Time increases from right to left.

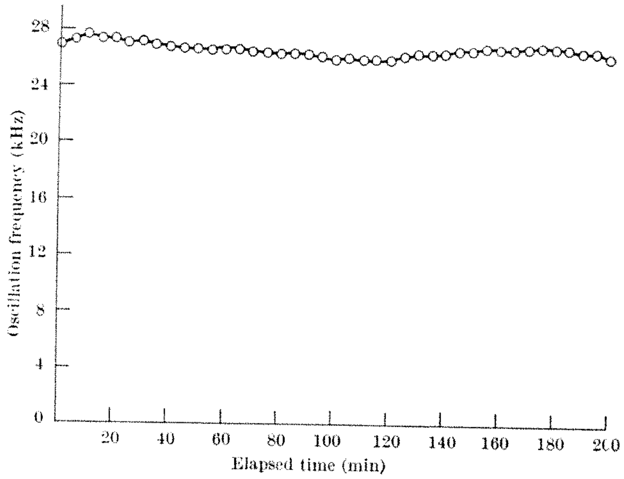

Fig. 3. Observed oscillation frequency for a 200 min experimental run.

It is a highly significant fact that, if the continuity equation oscillation is responsible for periodic astrophysical phenomena, a triggering signal is not required for the production of synchronized pulses, and the size of the pulsating object is not limited to the product of the fastest observed rise time and the speed of light. If the ionization rate parameters $(\sigma v)_{\rm ne}$ are the same, two spatially separated regions of partially ionized gas may behave like two independent clocks whose frequency of oscillation is determined only by the product $\bar{n}_e\bar{n}$. Electrons moving from one part of the region to another would be expected to bring the whole into phase, after an initial period of adjustment.

If a star possesses a strong magnetic field, it would undoubtedly also possess an extensive magnetosphere of trapped particles. The continuity equation oscillation may take place in the region of approximately constant $\bar{n}_e\bar{n}$ at the base of the magnetosphere, where the exponentially decreasing (with radius) neutral atmospheric density meets the increasing density of charged particles. Pulses of charged particles produced in such a region may well be heated by turbulent processes to the point where they emit pulses of r.f. and/or visible synchrotron radiation[13] in the stellar magnetic field.

Equation (3) implies that if the plasma were produced in some past catastrophic event, such as a supernova explosion, the period should lengthen as the electron number density decreases with time. This is consistent with the tendency for pulsar periods to lengthen[14,15]. It would not be too surprising to observe periods that shortened and then lengthened again as a flare or other event dumped an increased load of electrons into the stellar magnetosphere.

A similar mechanism may occur in the outer regions of a planet with a magnetosphere, at a radius where the particle mean free paths are comparable with the thickness of the oscillating layer. The periodic fluctuations of the charged particle number density would give rise to a periodic loading of the magnetospheric magnetic field lines, which in turn would cause geomagnetic micropulsations over a large region of the planetary surface. I have discussed further the application of the continuity equation oscillation mechanism to geomagnetic micropulsations and quasi-periodic scintillations of the interstellar medium in some unpublished work.

Precession in a Disk Dynamo Model of the Earth's Dipole Field

THE Earth's dipole field has undergone more polarity reversals than was hitherto supposed, according to recent studies of geomagnetic data[1,2]. It has been estimated[2] that the Laschamp polarity interval lasted only about 20,000 yr, and Cox[3] has predicted that several intervals shorter than 50,000 yr remain to be discovered. I suggest here that such polarity intervals may be connected with the effects of precession acting on the Earth's dynamo process.

The question of whether precessional torques can affect the motion of the core has been widely discussed[4-7], following the work of Poincaré[8]. I am assuming that precession does affect the dynamo process in the core, and I show that this assumption may not be inconsistent with the recent data on short polarity intervals.

In his investigation of the lengths of polarity intervals, Cox[3] used the system of two coupled disk dynamos, which is known to exhibit magnetic field reversals[9-11]. One difficulty faced by this model is that the period of oscillation of the field is at most 50 yr, far too short to account for polarity intervals of the order of 10^4 yr. Bullard[4] suggested that the introduction of a Coriolis force might increase the periods considerably, but it is difficult to see how the effect of this force could be analysed without complicating the model considerably.

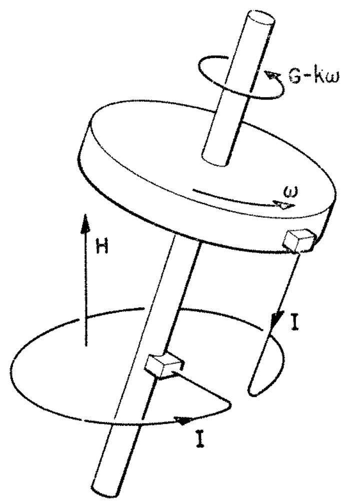

Fig. 1. Diagram of the precessing disk dynamo. The system is self-exciting if the directions of current I, magnetic field H and spin ω are as shown.
